Provided herein are devices comprising one or more cells, and methods for fabrication thereof. The devices may be electrochemical devices. The devices may include three-dimensional supercapacitors. The devices may be microdevices such as, for example, microsupercapacitors. In some embodiments, the devices are three-dimensional hybrid microsupercapacitors. The devices may be configured for high voltage applications. In some embodiments, the devices are high voltage microsupercapacitors. In certain embodiments, the devices are high voltage asymmetric microsupercapacitors. In some embodiments, the devices are integrated microsupercapacitors for high voltage applications.

DEVICES AND METHODS FOR HIGH VOLTAGE AND SOLAR APPLICATIONS

CROSS-REFERENCE
[0001] This application claims the benefit of U.S. Provisional Application No. 62/312,408 filed Mar. 23, 2016, and U.S. Provisional Application No. 62/421,920 filed Nov. 14, 2016, which applications are incorporated herein in their entirety by reference.

BACKGROUND
[0002] As a result of the rapidly growing energy needs of modern life, the development of high performance energy storage devices has gained significant attention.
[0003] Supercapacitors are promising energy storage devices with properties intermediate between those of batteries and traditional capacitors, but they are being improved more rapidly than either. Over the past couple of decades, supercapacitors have become key components of everyday products by replacing batteries and capacitors in an increasing number of applications. Their high power density and excellent low temperature performance have made them the technology of choice for application in back-up power, cold starting, flash cameras, regenerative braking, and hybrid electric vehicles. The future growth of this technology depends on further improvements in many areas, including energy density, power density, calendar life, cycle life, and production cost.

SUMMARY
[0004] The instant inventors have recognized a need for improved design and integration of hybrid materials into microsupercapacitors (e.g., due to complicated microfabrication techniques that may involve building 3D microelectrodes with micrometer separations).
[0005] The present disclosure provides a simple, yet versatile, technique for the fabrication of microdevices such as, for example, 3D hybrid microsupercapacitors. In some embodiments, such 3D hybrid microsupercapacitors are based on interconnected corrugated carbon-based network (ICCN) and MnO₂. In some embodiments, the microdevices herein enable a capacitance per footprint (e.g., an ultrahigh capacitance per footprint) approaching about 400 mF/cm². In some embodiments, microdevices herein provide an energy density of up to about 22 Wh/L (e.g., more than twice that of lithium thin film batteries). These developments are promising, among other examples, for microelectronic devices such as biomedical sensors and radio frequency identification (RFID) tags (e.g., where high capacity per footprint is crucial).
[0006] The present disclosure provides a method for the preparation and/or integration of microdevices for high voltage applications. In some embodiments, the present disclosure provides a method for the direct preparation and integration of asymmetric microsupercapacitors for high voltage applications. The microsupercapacitors may comprise an array of separate electrochemical cells. In some embodiments, the array of separate electrochemical cells can be directly fabricated in the same plane and in one step. This configuration may provide very good control over the voltage and current output. In some embodiments, the array can be integrated with solar cells for efficient solar energy harvesting and storage. In some embodiments, the devices are integrated microsupercapacitors for high voltage applications. In certain embodiments, the devices are asymmetric microsupercapacitors for high voltage applications (high voltage asymmetric microsupercapacitors). In some embodiments, the array comprises one or more electrochemical cells with at least one ICCN/MnO₂ hybrid electrode.

[0007] An aspect of the present disclosure provides an approach for fabrication of hybrid laser-scribed graphene (LSG)-MnO₂ 3D microsupercapacitors and microsupercapacitors. In some embodiments, the supercapacitors and/or microsupercapacitors can be compact, reliable, energy dense, or any combination thereof. In other embodiments, the supercapacitors and/or microsupercapacitors can charge quickly, possess long lifetime, or any combination thereof. Given the use of MnO₂ in alkaline batteries (selling approximately 10 billion units per year) and the scalability of graphene-based materials, graphene/MnO₂ hybrid electrodes may offer promise for real world applications.

[0008] An aspect of the present disclosure provides an electrochemical system comprising a plurality of interconnected electrochemical cells, each electrochemical cell comprising a first electrode and a second electrode, wherein at least one of the first electrode and the second electrode comprises an interconnected corrugated carbon-based network (ICCN). In some embodiments, the electrochemical system is capable of outputting a voltage of at least 5 V to about 500 V. In some embodiments, the electrochemical system is capable of outputting a voltage of at least about 5 V. In some embodiments, the electrochemical system is capable of outputting a voltage of at least about 100 V. In some embodiments, the electrochemical system is capable of outputting a voltage of at about 5 V to about 10 V, about 5 V to about 50 V, about 5 V to about 100 V, or about 5 V to about 200 V, about 5 V to about 300 V, about 5 V to about 400 V, about 5 V to about 500 V, about 10 V to about 50 V, about 10 V to about 100 V, about 10 V to about 200 V, about 10 V to about 300 V, about 10 V to about 400 V, about 10 V to about 500 V, about 20 V to about 100 V, about 20 V to about 200 V, about 20 V to about 300 V, about 20 V to about 400 V, about 20 V to about 500 V, about 300 V to about 400 V, or about 500 V to about 500 V.

[0009] In some embodiments, the plurality of interconnected electrochemical cells comprises at least one hybrid supercapacitor cell. In some embodiments, the plurality of interconnected electrochemical cells is an array of hybrid microsupercapacitors. In some embodiments, the plurality of interconnected electrochemical cells is an array of microsupercapacitors fabricated by light scribing.

[0010] In some embodiments, the electrochemical system further comprises an electrolyte disposed between the first electrode and the second electrode. In some embodiments, the electrolyte is an aqueous electrolyte. In some embodiments, the system further comprises a solar cell in electrical communication with the plurality of interconnected electrochemical cells. In some embodiments, the solar cell is a copper indium gallium selenium (CIGS) cell or an organic photovoltaic cell.

[0011] In some embodiments, the electrochemical system comprises a planar array of interconnected electrochemical
cells, wherein each electrochemical cell comprises at least two electrodes, wherein each electrode comprises a carbonaceous material, wherein at least one electrode further comprises a pseudocapacitive material. In some embodiments, the carbonaceous material comprises an interconnected corrugated carbon-based network (ICCN), a laser scribed graphene (LSG) or any combination thereof. In some embodiments, each electrochemical cell comprises two electrodes, and wherein each electrode comprises a carbonaceous material and a pseudocapacitive material. In some embodiments, the pseudocapacitive material comprises MnO₂, RuO₂, Co₃O₄, NiO, Fe₃O₄, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof. In some embodiments, the array of electrochemical cells is arranged in an interdigitated structure. In some embodiments, the electrochemical system further comprises an electrolyte disposed between the first electrode and the second electrode. In some embodiments, the electrochemical system further comprises a current collector attached to an electrode. In some embodiments, at least one electrochemical cell is capable of outputting a voltage of at least about 5 volts. In some embodiments, the electrochemical system is capable of outputting a voltage of at least 100 volts. In some embodiments, an electrochemical cell has an energy density of at least about 22 watt-hours per liter (Wh/L). In some embodiments, the array of electrochemical cells has a capacitance per footprint of at least about 380 millifarads per square centimeter (mF/cm²). In some embodiments, the array of electrochemical cells has a volumetric capacitance of at least about 1,100 farads per cubic centimeter (F/cm³).

Another aspect of the present disclosure provides a supercapacitor comprising an array of supercapacitor cells. In some embodiments, the array of supercapacitor cells comprises at least one hybrid supercapacitor cell. In some embodiments, the array of supercapacitor cells is an array of hybrid supercapacitor cells.

In some embodiments, the array of supercapacitor cells is capable of outputting a voltage of about 5 V to about 100 V. In some embodiments, the array of supercapacitor cells is capable of outputting a voltage of at least about 5 V. In some embodiments, the array of supercapacitor cells is capable of outputting a voltage of about 5 V to about 10 V, about 5 V to about 20 V, about 5 V to about 30 V, about 5 V to about 40 V, about 5 V to about 50 V, about 5 V to about 60 V, about 5 V to about 70 V, about 5 V to about 80 V, about 5 V to about 90 V, about 5 V to about 100 V, about 10 V to about 20 V, about 10 V to about 30 V, about 10 V to about 40 V, about 10 V to about 50 V, about 10 V to about 60 V, about 10 V to about 70 V, about 10 V to about 80 V, about 10 V to about 90 V, about 10 V to about 100 V, about 20 V to about 30 V, about 20 V to about 40 V, about 20 V to about 50 V, about 20 V to about 60 V, about 20 V to about 70 V, about 20 V to about 80 V, about 20 V to about 90 V, about 20 V to about 100 V, about 30 V to about 40 V, about 30 V to about 50 V, about 30 V to about 60 V, about 30 V to about 70 V, about 30 V to about 80 V, about 30 V to about 90 V, about 30 V to about 100 V, about 40 V to about 50 V, about 40 V to about 60 V, about 40 V to about 70 V, about 40 V to about 80 V, about 40 V to about 90 V, about 40 V to about 100 V, about 50 V to about 60 V, about 50 V to about 70 V, about 50 V to about 80 V, about 50 V to about 90 V, about 50 V to about 100 V, about 60 V to about 70 V, about 60 V to about 80 V, about 60 V to about 90 V, about 60 V to about 100 V, about 70 V to about 80 V, about 70 V to about 90 V, about 70 V to about 100 V, about 80 V to about 90 V, about 80 V to about 100 V, or about 90 V to about 100 V.

In some embodiments, the supercapacitor has an energy density of about 10 Wh/L to about 80 Wh/L. In some embodiments, the supercapacitor has an energy density of at least about 10 Wh/L. In some embodiments, the supercapacitor has an energy density of about 20 Wh/L to about 40 Wh/L, about 10 Wh/L to about 30 Wh/L, about 10 Wh/L to about 40 Wh/L, about 10 Wh/L to about 50 Wh/L, about 10 Wh/L to about 60 Wh/L, about 10 Wh/L to about 70 Wh/L, about 10 Wh/L to about 80 Wh/L, about 20 Wh/L to about 30 Wh/L, about 20 Wh/L to about 40 Wh/L, about 20 Wh/L to about 50 Wh/L, about 20 Wh/L to about 60 Wh/L, about 20 Wh/L to about 70 Wh/L, about 20 Wh/L to about 80 Wh/L, about 20 Wh/L to about 90 Wh/L, about 20 Wh/L to about 100 Wh/L, about 30 Wh/L to about 40 Wh/L, about 30 Wh/L to about 50 Wh/L, about 30 Wh/L to about 60 Wh/L, about 30 Wh/L to about 70 Wh/L, about 30 Wh/L to about 80 Wh/L, about 30 Wh/L to about 90 Wh/L, about 30 Wh/L to about 100 Wh/L, about 40 Wh/L to about 50 Wh/L, about 40 Wh/L to about 60 Wh/L, about 40 Wh/L to about 70 Wh/L, about 40 Wh/L to about 80 Wh/L, about 40 Wh/L to about 90 Wh/L, about 40 Wh/L to about 100 Wh/L, about 50 Wh/L to about 60 Wh/L, about 50 Wh/L to about 70 Wh/L, about 50 Wh/L to about 80 Wh/L, about 50 Wh/L to about 90 Wh/L, about 50 Wh/L to about 100 Wh/L, about 60 Wh/L to about 70 Wh/L, about 60 Wh/L to about 80 Wh/L, about 60 Wh/L to about 90 Wh/L, about 60 Wh/L to about 100 Wh/L, about 70 Wh/L to about 80 Wh/L, about 70 Wh/L to about 90 Wh/L, about 70 Wh/L to about 100 Wh/L, about 80 Wh/L to about 90 Wh/L, about 80 Wh/L to about 100 Wh/L, or about 90 Wh/L to about 100 Wh/L.

[0015] In some embodiments, the at least one supercapacitor cell has an energy density at least about 6 times greater than an energy density of a carbon-based non-hybrid supercapacitor cell. In some embodiments, the at least one hybrid supercapacitor cell comprises at least one electrode comprising (i) a carbonaceous material and (ii) a pseudocapacitive metal or metal oxide material. In some embodiments, the at least one hybrid supercapacitor cell comprises at least one electrode comprising an interconnected corrugated carbon-based network (ICCN) and MnO₂. In some embodiments, the at least one hybrid supercapacitor cell comprises symmetric or asymmetric electrodes.

In some embodiments, the array of supercapacitor cells is arranged in an interdigitated structure. In some embodiments, the array of supercapacitor cells has a capacitance per footprint of about 250 mF/cm² to about 600 mF/cm². In some embodiments, the array of supercapacitor cells has a capacitance per footprint of at least about 250 mF/cm². In some embodiments, the array of supercapacitor cells has a capacitance per footprint of about 250 mF/cm² to about 300 mF/cm², about 250 mF/cm² to about 350 mF/cm², about 250 mF/cm² to about 400 mF/cm², about 250 mF/cm² to about 450 mF/cm², about 250 mF/cm² to about 500 mF/cm², about 250 mF/cm² to about 550 mF/cm², about 250 mF/cm² to about 600 mF/cm², about 300 mF/cm² to about 350 mF/cm², about 300 mF/cm² to about 400 mF/cm², about 300 mF/cm² to about 450 mF/cm², about 300 mF/cm² to about 500 mF/cm², about 300 mF/cm² to about 550 mF/cm², about 300 mF/cm² to about 600 mF/cm², about 350 mF/cm² to about 400 mF/cm², about 350 mF/cm² to about 450 mF/cm², about 350 mF/cm² to about 500 mF/cm², about 350 mF/cm² to about 550 mF/cm², about 350 mF/cm² to about 600 mF/cm², about 400 mF/cm² to about 450 mF/cm², about 400 mF/cm² to about 500 mF/cm², about 400 mF/cm² to about 550 mF/cm², about 400 mF/cm² to about 600 mF/cm², about 500 mF/cm² to about 600 mF/cm².
In some embodiments, the array of supercapacitors maintains the capacitance even at high charge-discharge rates. In some embodiments, the array of supercapacitors maintains the capacitance at a charge-discharge rate corresponding to a current density of about 5,000 mA/cm² to about 20,000 mA/cm². In some embodiments, the array of supercapacitors maintains the capacitance at a charge-discharge rate corresponding to a current density of about 5,000 mA/cm² to about 10,000 mA/cm², about 5,000 mA/cm² to about 12,500 mA/cm², about 5,000 mA/cm² to about 15,000 mA/cm², about 5,000 mA/cm² to about 17,500 mA/cm², about 5,000 mA/cm² to about 20,000 mA/cm², about 7,500 mA/cm² to about 10,000 mA/cm², about 5,000 mA/cm² to about 12,500 mA/cm², about 5,000 mA/cm² to about 15,000 mA/cm², about 5,000 mA/cm² to about 17,500 mA/cm², about 5,000 mA/cm² to about 20,000 mA/cm², about 7,500 mA/cm² to about 10,000 mA/cm², about 5,000 mA/cm² to about 12,500 mA/cm², about 5,000 mA/cm² to about 15,000 mA/cm², about 5,000 mA/cm² to about 17,500 mA/cm², about 5,000 mA/cm² to about 20,000 mA/cm², about 7,500 mA/cm² to about 10,000 mA/cm², about 5,000 mA/cm² to about 12,500 mA/cm², about 5,000 mA/cm² to about 15,000 mA/cm², about 5,000 mA/cm² to about 17,500 mA/cm², about 5,000 mA/cm² to about 20,000 mA/cm², about 7,500 mA/cm² to about 10,000 mA/cm², about 5,000 mA/cm² to about 12,500 mA/cm², about 5,000 mA/cm² to about 15,000 mA/cm², about 5,000 mA/cm² to about 17,500 mA/cm², about 5,000 mA/cm² to about 20,000 mA/cm², or about 17,500 mA/cm² to about 20,000 mA/cm².

In some embodiments, the array of supercapacitors maintains the capacitance at a charge-discharge rate corresponding to a scan rate of about 5,000 mV/s to about 20,000 mV/s. In some embodiments, the array of supercapacitors maintains the capacitance at a charge-discharge rate corresponding to a scan rate of at least about 5,000 mV/s. In some embodiments, the array of supercapacitors maintains the capacitance at a charge-discharge rate corresponding to a scan rate of about 5,000 mV/s to about 6,250 mV/s, about 5,000 mV/s to about 7,500 mV/s, about 5,000 mV/s to about 10,000 mV/s, about 5,000 mV/s to about 11,250 mV/s, about 5,000 mV/s to about 12,500 mV/s, about 5,000 mV/s to about 15,000 mV/s, about 5,000 mV/s to about 16,250 mV/s, about 5,000 mV/s to about 17,500 mV/s, about 5,000 mV/s to about 20,000 mV/s, about 6,250 mV/s to about 7,500 mV/s, about 6,250 mV/s to about 10,000 mV/s, about 6,250 mV/s to about 11,250 mV/s, about 6,250 mV/s to about 12,500 mV/s, about 6,250 mV/s to about 15,000 mV/s, about 6,250 mV/s to about 16,250 mV/s, about 6,250 mV/s to about 17,500 mV/s, about 6,250 mV/s to about 20,000 mV/s, about 7,500 mV/s to about 10,000 mV/s, about 7,500 mV/s to about 11,250 mV/s, about 7,500 mV/s to about 12,500 mV/s, about 7,500 mV/s to about 15,000 mV/s, about 7,500 mV/s to about 16,250 mV/s, about 7,500 mV/s to about 17,500 mV/s, about 7,500 mV/s to about 20,000 mV/s, about 10,000 mV/s to about 11,250 mV/s, about 10,000 mV/s to about 12,500 mV/s, about 10,000 mV/s to about 15,000 mV/s, about 10,000 mV/s to about 16,250 mV/s, about 10,000 mV/s to about 17,500 mV/s, about 10,000 mV/s to about 20,000 mV/s, about 11,250 mV/s to about 12,500 mV/s, about 11,250 mV/s to about 15,000 mV/s, about 11,250 mV/s to about 16,250 mV/s, about 11,250 mV/s to about 17,500 mV/s, about 11,250 mV/s to about 20,000 mV/s, about 12,500 mV/s to about 15,000 mV/s, about 12,500 mV/s to about 16,250 mV/s, about 12,500 mV/s to about 17,500 mV/s, about 12,500 mV/s to about 20,000 mV/s, about 15,000 mV/s to about 16,250 mV/s, about 15,000 mV/s to about 17,500 mV/s, about 15,000 mV/s to about 20,000 mV/s, about 16,250 mV/s to about 17,500 mV/s, about 16,250 mV/s to about 20,000 mV/s, or about 17,500 mV/s to about 20,000 mV/s.

In some aspects provide a system comprising the supercapacitor, wherein the array of supercapacitor cells is in electrical communication with at least one solar cell, and wherein the at least one solar cell includes a copper indium gallium selenium (CIGS) cell, an organic photovoltaic cell, or a combination thereof.

Another aspect of the present disclosure provides a method for fabricating a supercapacitor comprising forming electrodes comprising laser scribing. In some embodiments, the method comprises forming electrodes comprising LightScribe writing on a film, wherein at least one of the electrodes is configured to store charge via one or more non-Faradaic processes, wherein at least one of the electrodes comprises a pseudocapacitive material configured to store charge via one or more Faradaic processes.

In some embodiments, the supercapacitor is capable of outputting a voltage of about 5 V to about 100 V. In some embodiments, the supercapacitor is capable of outputting a voltage of at least about 5 V. In some embodiments, the supercapacitor is capable of outputting a voltage of about 5 V to about 10 V, about 5 V to about 20 V, about 5 V to about 30 V, about 5 V to about 40 V, about 5 V to about 50 V, about 5 V to about 60 V, about 5 V to about 70 V, about 5 V to about 80 V, about 5 V to about 90 V, about 5 V to about 100 V, about 10 V to about 20 V, about 10 V to about 30 V, about 10 V to about 40 V, about 10 V to about 50 V, about 10 V to about 60 V, about 10 V to about 70 V, about 10 V to about 80 V, about 10 V to about 90 V, about 10 V to about 100 V, about 20 V to about 30 V, about 20 V to about 40 V, about 20 V to about 50 V, about 20 V to about 60 V, about 20 V to about 70 V, about 20 V to about 80 V, about 20 V to about 90 V, about 20 V to about 100 V, about 30 V to about 40 V, about 30 V to about 50 V, about 30 V to about 60 V, about 30 V to about 70 V, about 30 V to about 80 V, about 30 V to about 90 V, about 30 V to about 100 V, about 40 V to about 50 V, about 40 V to about 60 V, about 40 V to about 70 V, about 40 V to about 80 V, about 40 V to about 90 V, about 40 V to about 100 V, about 50 V to about 60 V, about 50 V to about 70 V, about 50 V to about 80 V, about 50 V to about 90 V, about 50 V to about 100 V, about 60 V to about 70 V, about 60 V to about 80 V, about 60 V to about 90 V, about 60 V to about 100 V, about 70 V to about 80 V, about 70 V to about 90 V, about 70 V to about 100 V, about 80 V to about 90 V, about 80 V to about 100 V, or about 90 V to about 100 V.

In some embodiments, the method further comprises selectively electrodepositing the pseudocapacitive material on at least one of the electrodes. In some embodiments, the method further comprises forming the electrodes by laser scribing graphite oxide films. In some embodiments, the method further comprises forming a porous interconnected corrugated carbon-based network (ICCN), wherein the porous ICCN comprises a plurality of carbon layers that are interconnected and expanded apart from one another to form a plurality of pores. In some embodiments, the method further comprises electrodepositing metallic nanoparticles within the plurality of pores. In some embodiments, the method further comprises forming the electrodes...
in an interdigitated pattern. In some embodiments, the pseudocapacitive material comprises MnO₂ nanoflowers. In some embodiments, a supercapacitor cell comprises (i) a first electrode comprising an ICCN and the pseudocapacitive material and (ii) a second electrode comprising the ICCN, thereby forming a supercapacitor cell with asymmetric electrodes. In some embodiments, a supercapacitor cell comprises (i) a first electrode comprising an ICCN and the pseudocapacitive material and (ii) a second electrode comprising the ICCN and the pseudocapacitive material, thereby forming a supercapacitor cell with symmetric electrodes. In some embodiments, the method further comprises directly fabricating an array of separate supercapacitor cells in the same plane and in one step.

[0023] In some embodiments, a method for fabricating an electrochemical system comprises: forming a carbonaceous film; forming a carbonaceous framework from the carbonaceous film; patterning the carbonaceous framework to form a planar array of two or more cells, wherein each cell comprises at least two electrodes, and electrodepositing a pseudocapacitive material onto a portion of the planar array. In some embodiments, the carbonaceous framework comprises graphene oxide (GO). In some embodiments, the carbonaceous film comprises a three-dimensional carbon framework comprising an interconnected corrugated carbon-based network (ICCN), a laser scribed graphene (LSG), or any combination thereof. In some embodiments, the forming of the carbonaceous framework from the carbonaceous film comprises light scribing. In some embodiments, the patterning the carbonaceous framework comprises light scribing. In some embodiments, the patterning the carbonaceous framework forms two or more interdigitated electrodes. In some embodiments, the array is a planar array. In some embodiments, the pseudocapacitive material comprises MnO₂, RuO₂, Co₃O₄, NiO, Fe₂O₃, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof. Some embodiments further comprise depositing an electrolyte on the carbonaceous framework. Some embodiments further comprise connecting the two or more cells.

[0024] In some embodiments, the light scribing is performed by a LightScribe DVD labeler through direct writing. In some embodiments, the light scribing is performed by a light beam whose frequency is about 1x10⁶ Hz to about 18x10⁶ Hz.

[0025] In some embodiments, the light scribing is performed by a light beam whose wavelength is about 350 nanometers (nm) to about 1,450 nanometers. In some embodiments, the light scribing is performed by a light beam whose wavelength is at least about 350 nanometers. In some embodiments, the light scribing is performed by a light beam whose wavelength is at most about 1,450 nanometers. In some embodiments, the light scribing is performed by a light beam whose wavelength is about 350 nanometers to about 1,450 nanometers. In some embodiments, the light scribing is performed by a light beam whose wavelength is about 350 nanometers to about 550 nanometers, about 350 nanometers to about 650 nanometers, about 350 nanometers to about 750 nanometers, about 350 nanometers to about 850 nanometers, about 350 nanometers to about 950 nanometers, about 450 nanometers to about 850 nanometers, about 450 nanometers to about 950 nanometers, about 450 nanometers to about 1,050 nanometers, about 450 nanometers to about 1,150 nanometers, about 450 nanometers to about 1,250 nanometers, about 450 nanometers to about 1,350 nanometers, about 450 nanometers to about 1,450 nanometers, about 450 nanometers to about 1,550 nanometers, about 450 nanometers to about 1,650 nanometers, about 450 nanometers to about 1,750 nanometers, about 450 nanometers to about 1,850 nanometers, about 450 nanometers to about 1,950 nanometers, about 50 mW to about 80 mW, about 60 mW to about 70 mW, about 60 mW to about 80 mW, or about 70 mW to about 80 mW.
In some embodiments, the supercapacitor is a three-dimensional hybrid microsupercapacitor. In some embodiments, the supercapacitor comprises three-dimensional interdigitated microsupercapacitors. In some embodiments, the supercapacitor comprises asymmetric microsupercapacitors. In some embodiments, the method further comprises forming a plurality of interdigitated electrodes into an array of microsupercapacitors. In some embodiments, the method further comprises integrating the array of microsupercapacitors with one or more solar cells.

In some embodiments, the one or more solar cells include a copper indium gallium selenide (CIGS) cell. In some embodiments, the one or more solar cells include an organic photovoltaic cell. In some embodiments, the plurality of interdigitated electrodes is configured to store charge via one or more non-Faradaic processes.

In some embodiments, the supercapacitor has a capacitance per footprint that is at least about 2 times greater than a commercial carbon supercapacitor. In some embodiments, the supercapacitor has a capacitance per footprint of about 0.3 F/cm² to about 0.8 F/cm². In some embodiments, the supercapacitor has a capacitance per footprint of at least about 0.3 F/cm² to about 0.4 F/cm², about 0.5 F/cm² to about 0.125 F/cm², about 0.125 F/cm² to about 0.175 F/cm², about 0.175 F/cm² to about 0.250 F/cm², about 0.250 F/cm² to about 0.375 F/cm², about 0.375 F/cm² to about 0.5 F/cm², about 0.5 F/cm² to about 0.625 F/cm², about 0.625 F/cm² to about 0.750 F/cm², about 0.750 F/cm² to about 0.875 F/cm², about 0.875 F/cm² to about 1.0 F/cm², about 1.0 F/cm² to about 1.125 F/cm², about 1.125 F/cm² to about 1.250 F/cm², about 1.250 F/cm² to about 1.375 F/cm², about 1.375 F/cm² to about 1.500 F/cm², about 1.500 F/cm² to about 1.625 F/cm², about 1.625 F/cm² to about 1.750 F/cm², about 1.750 F/cm² to about 2.000 F/cm², about 2.000 F/cm² to about 2.500 F/cm², about 2.500 F/cm² to about 3.000 F/cm², about 3.000 F/cm² to about 5.000 F/cm², and about 5.000 F/cm² to about 10,000 F/cm².

In some embodiments, the hybrid electrode that comprises the pseudocapacitive material and is configured to store charge via the one or more non-Faradaic processes.

In some embodiments, the hybrid electrode has a volumetric capacitance of about 500 F/cm³ to about 2000 F/cm³. In some embodiments, the hybrid electrode has a volumetric capacitance of about 500 F/cm³ to about 625 F/cm³, about 625 F/cm³ to about 750 F/cm³, about 750 F/cm³ to about 1000 F/cm³, about 1000 F/cm³ to about 1250 F/cm³, about 1250 F/cm³ to about 1500 F/cm³, about 1500 F/cm³ to about 1750 F/cm³, about 1750 F/cm³ to about 2000 F/cm³, about 2000 F/cm³ to about 2500 F/cm³, and about 2500 F/cm³ to about 3000 F/cm³.

Other goals and advantages of the invention will be further appreciated and understood when considered in conjunction with the following description and accompanying drawings. While the following description may contain specific details describing particular embodiments of the invention, this should not be construed as limitations to the scope of the invention but rather as an exemplification of preferable embodiments. For each aspect of the invention, many variations are possible as suggested herein that are known to those of ordinary skill in the art. A variety of changes and modifications can be made within the scope of the invention without departing from the spirit thereof.

**BRIEF DESCRIPTION OF DRAWINGS**

The novel features of the invention are set forth with particularity in the appended claims. A better understanding of the features and advantages of the present invention will be obtained by reference to the following detailed description that sets forth illustrative embodiments, in which the principles of the invention are utilized, and the accompanying drawings or figures (also “FIG.” and “Figs.” herein), of which:

**FIG. 1A** shows an example of an electrode comprising a compact thick film of metal oxide, in accordance with some embodiments.

**FIG. 1B** shows an example of an electrode comprising a nanostructured metal oxide films, in accordance with some embodiments.

**FIG. 1C** shows an example of an electrode with conductive materials added to the nanostructured metal oxide, in accordance with some embodiments.
FIG. 1D shows an example of an electrode comprising nanostructured metal oxide grown on 3D interconnected carbon-based networks (ICCNs) with high surface area and high electronic conductivity, in accordance with some embodiments.

FIG. 2A is an exemplary schematic diagram of a fabrication procedure for laser-scribed graphene (LSG)-MnO₂ electrodes, in accordance with some embodiments.

FIG. 2B provides exemplary digital photographs showing a GO film before and after laser scribing, in accordance with some embodiments.

FIG. 2C shows an exemplary graph of mass loading of MnO₂ versus deposition time, in accordance with some embodiments.

FIG. 2D shows exemplary variation of resistance of an LSG-MnO₂ electrode as a function of bending radius, in accordance with some embodiments.

FIG. 2E shows exemplary changes in resistance of an LSG-MnO₂ electrode under repeated bending cycles for a concave bend radius of 5 mm, and an exemplary inset photograph showing flexibility of an LSG-MnO₂ electrode, in accordance with some embodiments.

FIG. 3A shows an exemplary scanning electron microscopy (SEM) image of an LSG-MnO₂ electrode at low magnification, in accordance with some embodiments.

FIG. 3B shows an exemplary SEM image of an LSG-MnO₂ electrode at high magnification, in accordance with some embodiments.

FIG. 3C provides an exemplary SEM image that shows nanoflower morphology of electrodeposited MnO₂, in accordance with some embodiments.

FIG. 3D shows an exemplary cross-sectional SEM image of LSG-MnO₂, in accordance with some embodiments.

FIG. 3E shows an exemplary energy-dispersive X-ray spectroscopy (EDS) elemental mapping of C (red), Mn (blue), and O (green), in accordance with some embodiments.

FIG. 3F shows exemplary X-ray photoelectron spectroscopy (XPS) spectra of Mn 2p showing a doublet with a peak-to-peak separation of 11.6 eV, in accordance with some embodiments.

FIG. 3G shows exemplary XPS spectra of Mn 3s, in accordance with some embodiments.

FIG. 4A shows an exemplary schematic of an LSG-MnO₂ symmetric supercapacitor device, in accordance with some embodiments.

FIG. 4B shows exemplary cyclic voltammetry (CV) profiles for an LSG-MnO₂ (3 min) supercapacitor at different scan rates, in accordance with some embodiments.

FIG. 4C shows exemplary evolution of stack capacitance of LSG with various mass loadings of MnO₂ as a function of scan rate, in accordance with some embodiments.

FIG. 4D shows exemplary specific capacitance due to MnO₂ only as a function of the loadings measured at a scan rate of 1 mV/s, in accordance with some embodiments.

FIG. 4E shows exemplary charge-discharge curves of an LSG-MnO₂ (3 min) supercapacitor at different current densities, in accordance with some embodiments.

FIG. 4F shows exemplary change of stack capacitance of an LSG-MnO₂ (120 min) supercapacitor as a function of current density and data for CCG-MnO₂ (120 min) and Au—MnO₂ (120 min) supercapacitors are presented for comparison, in accordance with some embodiments.

FIG. 4G shows exemplary progression of real (C') and imaginary (C'') parts of stack capacitance of CCG as a function of frequency, in accordance with some embodiments.

FIG. 4H shows exemplary progression of real (C') and imaginary (C'') parts of stack capacitance of LSG as a function of frequency, in accordance with some embodiments.

FIG. 4I provides an exemplary comparison of an LSG-MnO₂ (120 min) hybrid capacitor with examples of an activated carbon supercapacitor (2.7 V/10 F), a pseudocapacitor (2.6 V/35 mF), and a lithium-ion hybrid capacitor (2.3 V/220 F), in accordance with some embodiments.

FIG. 5A is an exemplary schematic showing an example structure of an assembled supercapacitor device based on graphene-MnO₂ as positive electrode and LSG as negative electrode in 1.0 M Na₂SO₄ electrolyte, in accordance with some embodiments.

FIG. 5B shows exemplary CV curves of an asymmetric supercapacitor after increasing the potential window from 0.8 to 2.0 V, in accordance with some embodiments.

FIG. 5C shows exemplary charge-discharge curves of an asymmetric supercapacitor after increasing the potential window from 0.8 to 2.0 V, in accordance with some embodiments.

FIG. 5D shows exemplary change of the stack capacitance as a function of current density, in accordance with some embodiments.

FIG. 5E shows exemplary electrochemical performance of the device under different bending angles, in accordance with some embodiments.

FIG. 5F shows exemplary cycling stability of the device tested over 10,000 cycles at a scan rate of 1,000 mV/s, and change of equivalent series resistance (ESR) during cycling, in accordance with some embodiments.

FIGS. 6A-C illustratively show an exemplary fabrication process for an asymmetric microsupercapacitor device based on LSG-MnO₂ as positive electrode and LSG as negative electrode, in accordance with some embodiments.

FIG. 6D is an exemplary photograph showing the asymmetric microsupercapacitor, in accordance with some embodiments.

FIG. 6E is an exemplary optical microscope image showing the LSG-GO/LSG-MnO₂ interface, in accordance with some embodiments.

FIG. 6F is an exemplary SEM image of an interface between GO and LSG showing selective electrodeposition of MnO₂ on LSG only and the inset provides a magnified view of the GO and LSG area, in accordance with some embodiments.

FIG. 6G provides an exemplary comparison of stack capacitance of the supercapacitor between the sandwich structure and the planar interdigitated structure for an asymmetric MnO₂ deposition time 3 min device, in accordance with some embodiments.

FIG. 6H provides the exemplary stack and areal capacitance of LSG-MnO₂ supercapacitors with deposition times of 0 to 120 minutes.
FIG. 16 shows examples of supercapacitor arrays that are connected in series, parallel and in combinations of the two, in accordance with some embodiments.

FIG. 17 shows examples of electrochemical performance of asymmetric supercapacitor arrays, in accordance with some embodiments.

FIG. 18A shows an exemplary image of a LSG microsupercapacitor array wherein graphene is used to connect the supercapacitor cells, in accordance with some embodiments.

FIG. 18B shows an exemplary image of a flexed LSG microsupercapacitor array wherein graphene is used to connect the supercapacitor cells, in accordance with some embodiments.

DETAILED DESCRIPTION

Provided herein are devices comprising one or more cells, and methods for fabrication thereof. The devices may be electrochemical devices. The devices may include three-dimensional supercapacitors. The devices may be microdevices such as, for example, microsupercapacitors. In some embodiments, the devices are three-dimensional hybrid microsupercapacitors. The devices may be configured for high voltage applications (e.g., microdevices for high voltage applications). In some embodiments, the devices are high voltage microsupercapacitors. In certain embodiments, the devices are high voltage asymmetric microsupercapacitors. In some embodiments, the devices are integrated microsupercapacitors for high voltage applications.

The present disclosure provides systems and methods for direct preparation of devices (e.g., high-voltage devices) such as, for example, high-voltage supercapacitors. The high-voltage supercapacitors may include microsupercapacitors. The high-voltage devices may be prepared in a single step. The high-voltage devices may be prepared using one package. The high-voltage devices may be prepared in a single step and using one package. One package may advantageously be used instead of a plurality (e.g., instead of hundreds in the traditional modules).

A high-voltage device (e.g., a high-voltage supercapacitor) may have a voltage of greater than or equal to about 5 volts (V), 10 V, 15 V, 20 V, 30 V, 40 V, 50 V, 60 V, 70 V, 80 V, 90 V, 100 V, 110 V, 120 V, 130 V, 140 V, 150 V, 160 V, 170 V, 180 V, 190 V, 200 V, 210 V, 220 V, 230 V, 240 V, 250 V, 260 V, 270 V, 280 V, 290 V, 300 V, 310 V, 320 V, 330 V, 340 V, 350 V, 360 V, 370 V, 380 V, 390 V, 400 V, 410 V, 420 V, 430 V, 440 V, 450 V, 460 V, 470 V, 480 V, 490 V, 500 V, 510 V, 520 V, 530 V, 540 V, 550 V, 560 V, 570 V, 580 V, 590 V, 600 V, 650 V, 700 V, 750 V, 800 V, 850 V, 900 V, 950 V, 1,000 V, 1,050 V, 1,100 V, 1,150 V, 1,200 V, 1,250 V, 1,300 V, 1,350 V, 1,400 V, 1,450 V, or 1,500 V.
In some embodiments, a high-voltage or supercapacitor may have a voltage of at least about 100 V. In some embodiments, a high-voltage device or supercapacitor may have a voltage of at least about 180 V. In some embodiments, a high-voltage device or supercapacitor may have a voltage of less than or equal to about 600 V, 550 V, or 500 V. In some embodiments, a high-voltage device or supercapacitor may have a voltage of from about 100 V to 540 V, from 180 V to 540 V, from 100 V to 200 V, from 100 V to 300 V, from 180 V to 300 V, from 100 V to 400 V, from 180 V to 400 V, from 100 V to 500 V, from 180 V to 500 V, from 100 V to 600 V, from 180 V to 700 V, from 180 V to 700 V, from 100 V to 1,000 V, or from 150 V to 1,100 V.

High-voltage devices of the disclosure may comprise interconnected cells. In some embodiments, the cells can be electrochemical cells. In some embodiments, the cells can be individual supercapacitor cells. The cells may be interconnected to achieve a high voltage and/or for other purposes. Any aspects of the disclosure described in relation to a microsupercapacitor may equally apply to a supercapacitor at least in some configurations, and vice versa. In some embodiments, the supercapacitor cells may be microsupercapacitor cells. A cell may comprise symmetric or asymmetric electrodes.

A plurality of cells may be interconnected to form supercapacitors and/or other devices. In some embodiments, the devices can be batteries and/or various types of capacitors. In some embodiments, at least about 2, 5, 10, 20, 30, 40, 50, 75, 100, 125, 150, 200, 250, 300, 350, 400, 500, 600, 700, 800, 900, 1000, 1500, 2000, or more cells may be interconnected. In some embodiments, between about 50 and 300 cells may be interconnected. In some embodiments, the cells are connected in series. In some embodiments, the cells are connected in parallel. In some embodiments, the cells are connected in series and in parallel.

A supercapacitor may operate using one or more charge storage mechanisms. In some embodiments, the supercapacitor may operate using pseudocapacitor charge storage mechanisms. In some embodiments, the supercapacitor may operate using electric double-layer capacitor (EDLC) charge storage mechanisms. In some embodiments, the supercapacitor may operate using a combination of pseudocapacitor and electric double-layer capacitor (EDLC) charge storage mechanisms. In some embodiments, charge may be stored with the aid of both Faradic and non-Faradic processes. Such a supercapacitor may be referred to as a hybrid supercapacitor. In some embodiments, hybrid charge storage mechanism(s) occur at a single electrode. In some embodiments, hybrid charge storage mechanism(s) occur at both electrodes. Hybrid supercapacitors may comprise symmetric or asymmetric electrodes.

A cell may comprise an electrolyte. In some embodiments, the cell is a supercapacitor cell. Electrolytes may include aqueous electrolytes, organic electrolytes, ionic liquid-based electrolytes, or any combination thereof. In some embodiments, the electrolyte may be liquid, solid, and/or a gel. In some embodiments, an ionic liquid may be hybridized with another solid component to form a gel-like electrolyte (also “ionogel” herein). The solid component may be a polymer. The solid component may be silica. In some embodiments, the solid component can be fumed silica. An aqueous electrolyte may be hybridized with a polymer to form a gel-like electrolyte (also “hydrogel” and “hydrogel-polymer” herein). An organic electrolyte may be hybridized with a polymer to form a gel-like electrolyte.

Electrolytes may comprise aqueous potassium hydroxide; hydrogel comprising poly(vinyl alcohol) (PVA)-H₂SO₄ or PVA-H₃PO₄; aqueous electrolyte of phosphoric acid (H₃PO₄); tetraethyl ammonium tetrafluoroborate (TEABF₄) dissolved in acetonitrile, 1-ethyl-3-methylimidazoliumtetrafluoroborate (EMIMBF₄); ionogel comprising fumed silica (e.g., fumed silica nano-powder) mixed with an ionic liquid (e.g., 1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide (BMIIMNTf₂)); and the like. Such electrolytes may provide a range of voltage windows, including at least about 0.5 V, 1 V, 2 V, 3 V, 4 V, or more. In some embodiments, the ionogel comprising fumed silica nano-powder with the ionic liquid BMIIMNTf₂ may provide a voltage window of about 2.5 V. In some embodiments, hydrogel-polymer electrolytes may provide a voltage window of about 1 V. In some embodiments, a cell comprises an aqueous electrolyte.

The active material in the electrodes may comprise carbonaceous materials, one or more metal oxides, and/or other suitable materials. In some embodiments, the active material in the electrodes can be carbon. In some embodiments, the carbon can comprise activated carbon, graphene, interconnected corrugated carbon-based network (ICCN), or any combination thereof. The active material in the electrodes may comprise a highly conductive and high surface area laser-scribed graphene (LSG) framework that is a form of interconnected corrugated carbon-based network (ICCN). The ICCN may be produced from light scribing (e.g., laser scribing) of carbon-based films such as graphite oxide (GO). Any aspects of the disclosure described in relation to graphene (in the context of light scribed or three-dimensional materials) or LSG may equally apply to ICCN at least in some configurations, and vice versa.

An ICCN may comprise a plurality of expanded and interconnected carbon layers. For the purpose of this disclosure, in certain embodiments, the term “expanded,” referring to a plurality of carbon layers that are expanded apart from one another, means that a portion of adjacent ones of the carbon layers are separated by at least about 2 nanometers (nm). In some embodiments, at least a portion of adjacent carbon layers are separated by greater than or equal to about 2 nm, 3 nm, 4 nm, 5 nm, 6 nm, 7 nm, 8 nm, 9 nm, 10 nm, 15 nm, 20 nm, 25 nm, 30 nm, 35 nm, 40 nm, 45 nm, 50 nm, 55 nm, 60 nm, 65 nm, 70 nm, 75 nm, 80 nm, 85 nm, 90 nm, 95 nm, or 100 nm. In some embodiments, at least a portion of adjacent carbon layers are separated by less than about 3 nm, 4 nm, 5 nm, 6 nm, 7 nm, 8 nm 9 nm, 10 nm, 15 nm, 20 nm, 25 nm, 30 nm, 35 nm, 40 nm, 45 nm, 50 nm, 55 nm, 60 nm, 65 nm, 70 nm, 75 nm, 80 nm, 85 nm, 90 nm, 95 nm, or 100 nm. In some embodiments, at least a portion of adjacent carbon layers are separated by between about 2 nm and 10 nm, 2 nm and 25 nm, 2 nm and 50 nm, or 2 nm and 100 nm. In some embodiments, each of the plurality of carbon layers is a two-dimensional material with only one carbon atom of thickness. In some embodiments, each of the expanded and interconnected carbon layers may comprise at least one, or a plurality of corrugated carbon sheets that are each one atom thick. In another embodiment, each of the expanded and interconnected carbon layers comprises a plurality of corrugated carbon sheets. The thickness of the ICCN, as measured from cross-sectional scanning electron microscopy (SEM) and profilometry, can be found to be
around about 7.6 micrometer in one embodiment. In another embodiment, a range of thicknesses of the plurality of expanded and interconnected carbon layers making up the ICCN is from about 7 micrometer to 8 micrometer.

In some embodiments, the metallic nanoparticles may be metal particles that include, but are not limited to, Pt, Pd, Ag, Au, and combinations thereof. In some embodiments, the metallic nanoparticles may comprise MnO₂, RuO₂, Co₃O₄, NiO, Fe₂O₃, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof.

In some embodiments, a porous ICCN composite may be produced wherein a percentage of surface area coverage of the metallic nanoparticles onto the plurality of carbon layers ranges from about 10% to about 95%. In some embodiments, the percentage of surface area coverage of the metallic nanoparticles onto the plurality of carbon layers is at least about 15%, at least about 20%, at least about 25%, at least about 30%, at least about 35%, at least about 40%, at least about 45%, at least about 50%, at least about 60%, at least about 70%, at least about 80%, at least about 90%, or at least about 95%.

In some embodiments, a porous ICCN composite may be produced wherein the porous ICCN composite provides an energy density that ranges from about 2 Watt-hour/liter to about 41 Watt-hour/liter. In certain embodiments, the porous ICCN composite provides an energy density that is at least about 2 Watt-hour/liter, at least about 5 Watt-hour/liter, at least about 10 Watt-hour/liter, at least about 15 Watt-hour/liter, at least about 20 Watt-hour/liter, at least about 25 Watt-hour/liter, at least about 30 Watt-hour/liter, at least about 35 Watt-hour/liter, or at least about 40 Watt-hour/liter.

Methods of producing porous ICCN composite are provided herein. For example, in one embodiment, the method comprises: providing a film comprising a mixture of a metallic precursor and a carbon-based oxide; exposing at least a portion of the film to light to form a porous interconnected corrugated carbon-based network (ICCN) composite comprising: a plurality of carbon layers that are interconnected and expanded apart from one another to form a plurality of pores; and metallic nanoparticles disposed within the plurality of pores. The light may convert the metallic precursor to the metallic nanoparticles. Providing the film made of the mixture of the metallic precursor and the carbon-based oxide may comprise providing a solution comprising a liquid, the metallic precursor, and the carbon-based oxide; disposing the solution with the liquid, the metallic precursor, and the carbon-based oxide onto a substrate; and evaporating the liquid from the solution to form the film. The carbon-based oxide may be graphite oxide. The metallic nanoparticles may be, for example, particles of RuO₂, Co₃O₄, NiO, V₂O₅, Fe₂O₃, CuO, MoO₃, or any combination thereof.

In some embodiments, the metallic nanoparticles may comprise (e.g., comprise (or be) particles of) platinum (Pt), palladium (Pd), silver (Ag), gold (Au), or any combination thereof. In some embodiments, the metallic nanoparticles may be metal particles that include, but are not limited to, Pt, Pd, Ag, Au, and combinations thereof. In some embodiments, the metallic nanoparticles comprise MnO₂, RuO₂, Co₃O₄, NiO, Fe₂O₃, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof.

In some embodiments, a porous ICCN composite may be produced by providing a film comprising a mixture of a metallic precursor and a carbon-based oxide and exposing at least a portion of the film to light to form a porous interconnected corrugated carbon-based network (ICCN) composite. The porous ICCN composite may comprise a plurality of carbon layers that are interconnected and expanded apart from one another to form a plurality of pores, and metallic nanoparticles disposed within the plurality of pores. The light may convert the metallic precursor to the metallic nanoparticles. Providing the film made of the mixture of the metallic precursor and the carbon-based oxide may comprise providing a solution comprising a liquid, the metallic precursor, and the carbon-based oxide; disposing the solution with the liquid, the metallic precursor, and the carbon-based oxide onto a substrate; and evaporating the liquid from the solution to form the film. The carbon-based oxide may be graphite oxide. The metallic nanoparticles may be, for example, particles of RuO₂, Co₃O₄, NiO, V₂O₅, Fe₂O₃, CuO, MoO₃, or any combination thereof.

In some embodiments, a porous ICCN composite may be produced wherein a percentage of surface area coverage of the metallic nanoparticles onto the plurality of carbon layers ranges from about 10% to about 95%. In some embodiments, the percentage of surface area coverage of the metallic nanoparticles onto the plurality of carbon layers is at least about 15%, at least about 20%, at least about 25%, at least about 30%, at least about 35%, at least about 40%, at least about 45%, at least about 50%, at least about 60%, at least about 70%, at least about 80%, at least about 90%, or at least about 95%.

In some embodiments, a porous ICCN composite may be produced wherein the porous ICCN composite provides an energy density that ranges from about 2 Watt-hour/liter to about 41 Watt-hour/liter. In certain embodiments, the porous ICCN composite provides an energy density that is at least about 2 Watt-hour/liter, at least about 5 Watt-hour/liter, at least about 10 Watt-hour/liter, at least about 15 Watt-hour/liter, at least about 20 Watt-hour/liter, at least about 25 Watt-hour/liter, at least about 30 Watt-hour/liter, at least about 35 Watt-hour/liter, or at least about 40 Watt-hour/liter.

Methods of producing porous ICCN composite are provided herein. For example, in one embodiment, the method comprises: providing a film comprising a mixture of a metallic precursor and a carbon-based oxide; and exposing at least a portion of the film to light to form a porous interconnected corrugated carbon-based network (ICCN) composite comprising: a plurality of carbon layers that are interconnected and expanded apart from one another to form a plurality of pores; and metallic nanoparticles disposed within the plurality of pores, wherein the light converts the metallic precursor to the metallic nanoparticles. In further or additional embodiments, a method of producing porous ICCN composite is provided wherein providing the film made of the mixture of the metallic precursor and the carbon-based oxide comprises: providing a solution comprising a liquid, the metallic precursor, and the carbon-based
oxide; disposing the solution with the liquid, the metallic precursor, and the carbon-based oxide onto a substrate; and evaporating the liquid from the solution to form the film. In one embodiment, a method of producing porous interconnected corrugated carbon-based network (ICCN) composite is provided comprising: forming a porous ICCN comprising a plurality of carbon layers that are interconnected and expanded apart from one another to form a plurality of pores; and electrodepositing metallic nanoparticles within the plurality of pores. In another embodiment, the method comprises providing a film made of the mixture of the metallic precursor and the carbon-based oxide that comprises: providing a solution comprising a liquid, the metallic precursor, and the carbon-based oxide; disposing the solution with the liquid, the metallic precursor, and the carbon-based oxide onto a substrate; and evaporating the liquid from the solution to form the film. In certain applications, the carbon-based oxide is graphite oxide. The metallic nanoparticles may be particles of MnO₂, RuO₂, Co₃O₄, NiO, V₂O₅, Fe₃O₄, CuO, MoO₃, Ni(OH)₂, or any combination thereof.

[0113] In another aspect, methods for electrodepositing the metallic nanoparticles within the plurality of pores comprise: submerging the porous ICCN into an aqueous solution having a metal precursor; and applying an electrical current through the porous ICCN to electrodeposit the metallic nanoparticles into the plurality of pores. In some embodiments, the electrical current has a current density of at least about 250 mA/cm². In some embodiments, the electrical current has a current density of at least about 350 mA/cm², at least about 450 mA/cm², at least about 550 mA/cm², at least about 650 mA/cm²; at least about 750 mA/cm², or at least about 1,000 mA/cm².

[0114] The porous ICCN or ICCN composite may be formed by exposing the carbon-based oxide to light from a light source. The light source may comprise a laser, a flash lamp, or other equally high intensity sources of light capable of reducing the carbon-based oxide to the porous ICCN. Any aspects of the disclosure described in relation to laser-irradiated materials may equally apply to light-irradiated materials at least in some configurations, and vice versa.

[0115] Devices herein, including supercapacitors and/or microsupercapacitors, may be configured in different structures. In some embodiments, the devices may be configured in stacked structures, planar structures, spirally wound structures, or any combination thereof. In some embodiments, the devices may be configured to comprise stacked electrodes. In some embodiments, the devices may be configured to comprise interdigitated electrodes. In some embodiments, the devices may be configured in a sandwich structure or an interdigitated structure.

Supercapacitors

[0116] Supercapacitors may be classified according to their charge storage mechanism as either electric double-layer capacitors (EDLCs) or pseudocapacitors. EDLCs can store charge through rapid adsorption-desorption of electrolyte ions on high-surface-area carbon materials. Pseudocapacitors can store charge via fast and reversible Faradaic reactions near the surface of metal oxides or conducting polymers. In some embodiments, the supercapacitors comprise symmetric EDLCs with activated carbon electrodes and organic electrolytes that can provide cell voltages as high as 2.7 V. Although these EDLCs can exhibit high power density and excellent cycle life, they can suffer from low energy density because of the limited capacitance of carbon-based electrodes. Faradaic electrodes can have a specific pseudocapacitance (e.g., 300-1,000 F/g) that exceeds that of carbon-based EDLCs; however, their performance can degrade quickly upon cycling.

[0117] Hybrid systems may be used as an alternative to EDLCs and pseudocapacitors. Using both Faradaic and non-Faradaic processes to store charge, hybrid capacitors can achieve energy and power densities greater than EDLCs without sacrificing cycling stability and affordability that limits pseudocapacitors. Hybrid supercapacitors may comprise RuO₂, Co₃O₄, NiO, V₂O₅, Ni(OH)₂, MnO₂, or any combination thereof. MnO₂-based systems may be attractive, as MnO₂ is an earth-abundant and environmentally friendly material with a theoretical specific capacitance (e.g., a high theoretical specific capacitance) of 1,380 farads per gram (F/g); however, poor ionic (10⁻¹⁵ S/cm) and electronic (10⁻⁷-10⁻⁵ S/cm) conductivity of pristine MnO₂ can limit its electrochemical performance.

[0118] In some embodiments, ultrathin MnO₂ films that are a few tens of nanometers in thickness may be used. However, thickness and area-normalized capacitance of these electrodes may not be adequate for most applications.

[0119] In some embodiments, nanostructured manganese dioxide (MnO₂) may be incorporated on highly conductive support materials with high surface areas such as nickel nanocanoes, Mn nanotubes, activated carbon, carbon fabric, conducting polymers, carbon nanotubes or graphene. Specific capacitances of 148-410 F/g may be achieved under low charge-discharge rates but may decrease rapidly as the discharge rate is increased. Further, these materials may have low packing density with large pore volume, meaning that a huge amount of electrolyte is needed to build the device, which adds to the mass of the device without adding any capacitance. The energy density and power density on the device level may be very limited.

[0120] In some embodiments, hybrid electrodes based on 3D ICCN doped with MnO₂ nanopowders may be used. The structure of the ICCN substrate may be configured (e.g., rationally designed) to achieve high conductivity, suitable porosity, and/or high specific surface area. Such properties may result in not only a high gravimetric capacitance, but also improved volumetric capacitance. Furthermore, the high surface area of nanostructured MnO₂ can provide more active sites for Faradaic reactions and shorten ion diffusion pathways that are crucial for realizing its full pseudocapacitance. Hybrid supercapacitors based on these materials can achieve energy densities of, for example, up to about 42 Wh/L compared with about 7 Wh/L for state-of-the-art commercially available carbon-based supercapacitors. These ICCN-MnO₂ hybrid supercapacitors may use aqueous electrolytes and may be assembled in air without the need for the expensive dry rooms required for building today’s supercapacitors.

[0121] Reference will now be made to the figures. It will be appreciated that the figures and features therein are not necessarily drawn to scale.

Three-Dimensional (3D) Hybrid Supercapacitors and Microsupercapacitors

[0122] The present disclosure provides methods for engineering three-dimensional (3D) hybrid supercapacitors and microsupercapacitors. Such devices may be configured (e.g.,
engineered) for high-performance energy storage. In some embodiments, such devices are configured (e.g., engineered) for high-performance integrated energy storage. The 3D high-performance hybrid supercapacitors and microsupercapacitors may be based, for example, on ICCN and MnO₂. The 3D high-performance hybrid supercapacitors and microsupercapacitors may be configured by rationally designing the electrode microstructure and combining active materials with electrolytes that operate at high voltages. In some examples, this results in hybrid electrodes with a volumetric capacitance (e.g., an ultrahigh volumetric capacitance) of at least about 1,100 F/cm³, corresponding to a specific capacitance of the constituent MnO₂ of about 1,145 F/g, which is close to the theoretical value of 1,380 F/g. Energy density of the full device can vary, for example, between about 22 Wh/L and 42 Wh/L depending on the device configuration. In certain embodiments, such energy densities can be superior to (e.g., higher than) those of commercially available double-layer supercapacitors, pseudocapacitors, lithium-ion capacitors, and/or hybrid supercapacitors (e.g., commercially available hybrid supercapacitors comprising NIOOH positive electrode and activated carbon negative electrode, or PbO₂ positive electrode and activated carbon negative electrode) tested under the same conditions and/or comparable to that of lead acid batteries. These hybrid supercapacitors may use aqueous electrolytes and may be assembled in air without the need for expensive dry rooms required for building today’s supercapacitors.

[0123] In some examples, specific capacitance of the constituent metal or metal oxide (e.g., MnO₂) may be at least about 50%, 60%, 70%, 75%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% of the theoretical capacitance of the constituent metal or metal oxide (e.g., MnO₂). The electrode(s) may have such specific capacitance at a given mass loading of the constituent metal or metal oxide (e.g., MnO₂).

[0124] The electrode(s) may have a mass loading of the constituent metal or metal oxide (e.g., MnO₂) of at least about 5%, 10%, 13%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, or 99%. The electrode(s) may have a mass loading of the constituent metal or metal oxide (e.g., MnO₂) of less than or equal to about 5%, 10%, 13%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, or 99%. The electrode(s) may have a mass loading of the constituent metal or metal oxide (e.g., MnO₂) from about 5% to about 20%, from about 20% to about 50%, from about 10% to about 75%, or from about 10% to about 90%.

[0125] In some examples, a supercapacitor and/or microsupercapacitor herein can have a capacitance per footprint (also “areal capacitance” herein) of greater than or equal to about 0.3 F/cm², 0.4 F/cm², 0.5 F/cm², 0.6 F/cm², or 0.7 F/cm² (e.g., see TABLES 1-2). In some examples, a supercapacitor and/or microsupercapacitor herein can have a capacitance per footprint between about 0.3 F/cm² and 0.8 F/cm², 0.4 F/cm² and 0.8 F/cm², 0.5 F/cm² and 0.8 F/cm², 0.6 F/cm² and 0.8 F/cm², or 0.7 F/cm² and 0.8 F/cm². In some examples, a supercapacitor and/or microsupercapacitor herein can have a capacitance per footprint at least about 2, 3, 4, 5, 6, 7, 8, 9, or 10 times greater than a commercial carbon supercapacitor. In some examples, a hybrid electrode herein can have a volumetric capacitance of greater than or equal to about 50 F/cm³, 100 F/cm³, 150 F/cm³, 200 F/cm³, 400 F/cm³, 600 F/cm³, 800 F/cm³, 1,000 F/cm³, 1,100 F/cm³, 1,200 F/cm³, 1,300 F/cm³, 1,400 F/cm³, or 1,500 F/cm³ (e.g., when calculated based on the volume of the active material per electrode only).

[0126] In designing supercapacitor electrodes, special efforts can be made to ensure that they are capable of providing high energy density and high power density. This may require optimization of the preparation conditions to facilitate ionic and electronic transport within the electrodes as illustrated in FIGS. 1A-D. Rationally designing high-performance hybrid supercapacitors can include rationally designing high-energy-high-power hybrid supercapacitor electrodes.

[0127] FIGS. 1A-D schematically illustrate rational design of high-energy-high-power hybrid supercapacitor electrodes. The method can include improving ionic current (IC) and electronic current (EC) within the electrode (e.g., improving the IC and the EC can be key). To achieve high-energy and high-power supercapacitors, both the ionic and electronic currents within the electrodes may need to be facilitated. This can be very challenging (e.g., with metal oxide pseudocapacitors) because of low electrical conductivity and long ionic diffusion pathways of some metal oxide materials.

[0128] As illustrated in FIG. 1A, in a compact MnO₂, thick film electrode 101, only the top layer may be exposed to the electrolyte such that a limited amount of the active material is involved in charge storage.

[0129] Electrochemical utilization of electrodes can be improved by using nanostructured MnO₂, such as nanoparticles, nanorods, nanowires, and nanoflowers. As shown in FIG. 1B, the porous structure of a porous electrode 102 can increase or maximize the area of active material that is exposed to the electrolyte and thus available to discharge compared to a solid electrode surface. Although this system can exhibit higher energy density than the system in FIG. 1A, it can still suffer from the inherently low electrical conductivity of MnO₂ leading to low power output.

[0130] To improve the electrical conductivity of MnO₂, film, conductive materials such as carbon powder, carbon nanotubes, and graphene can be introduced into nanostructured MnO₂ electrodes 103. In such instances, the electronic charge carriers may need to move through small interparticle contact areas which exhibit additional resistance, resulting in poor electron transport from the electrode material to the current collector, as shown in FIG. 1C.

[0131] FIG. 1D shows an electrode obtained by growing MnO₂ nanostuctures onto a 3D interconnected macroporous ICCN framework 104 with high electrical conductivity and high surface area. In this structure, graphene or the conducting ICCN framework 104 can act as a 3D current collector to provide electron “superhighways” for charge storage and delivery, while the nanostructured MnO₂ can enable fast, reversible Faradaic reactions with short ionic diffusion pathways. Each MnO₂ nanoparticle can be electrically connected to the current collector so that substantially all of the nanoparticles can contribute to capacity with almost no “dead” mass.

[0132] FIGS. 2A-E show fabrication/synthesis and characterization of laser-scribed graphene (LSG)/MnO₂ electrodes 205 (e.g., 3D macroporous LSG-MnO₂ electrodes, wherein a highly conductive and high-surface-area 3D LSG
framework was integrated with MnO₂ as schematically illustrated in FIG. 2A. The 3D LSG framework (ICCN) 203 was produced from the laser scribing 202 of graphite oxide (GO) films 201, upon which the color changed from golden brown to black. The LSG framework was subsequently coated in situ with MnO₂ using an electrochemical deposition technique 204 (e.g., as described elsewhere herein).

FIG. 2B provides digital photographs showing an example of a GO film before and after laser scribing. The LSG can then be loaded with MnO₂, whose amount can be controlled by adjusting the deposition time (e.g., from about 3 minutes (min) to about 120 min). The ICCN electrode in FIG. 2B turns darker in color after electrodeposition, a visual indication of the loading of MnO₂.

Conductivity and mass loading of the active materials can have a significant impact on the electrochemical behavior of supercapacitor electrodes. The mass loading of MnO₂ can be controlled by adjusting the deposition current and deposition time. FIG. 2C shows that the MnO₂ loading changes almost linearly with the deposition time at an applied current of 0.25 mA/cm² and an average deposition rate estimated to be about 6 micrograms per minute (μG/min).

The LSG-MnO₂ electrodes can be monolithic and demonstrate superb mechanical integrity under large mechanical deformation (e.g., in addition to interesting electrical properties). FIG. 2D shows that an LSG-MnO₂ electrode can be bent significantly without damage. The foldability of LSG-MnO₂ electrodes was evaluated by measuring their electrical resistance under successive bending cycles. In this example, the resistance varies only slightly up to a bending radius of 5.0 mm and can be completely recovered after straightening no matter whether the bending is positive (convex) or negative (concave). As shown in FIG. 2E, after 1,000 cycles of bending and straightening at a concave bend radius of 5.0 mm, the resistance has increased by only about 2.8%.

FIGS. 3A-G show examples of morphological and structural characterization of LSG-MnO₂ electrodes. The evolution of morphology corresponding to different deposition times was examined by scanning electron microscopy (SEM) (FIGS. 3A-D). The SEM micrographs show the general morphology and detailed microstructure of a typical sample prepared by 120 min of deposition. MnO₂ has been uniformly coated onto the surface of graphene throughout the entire film. In this example, the electrodeposited MnO₂ particles show a nanoflower-shaped hierarchical architecture with a clear interface between MnO₂ and the ICCN substrate. Close inspection of the MnO₂ nanoflowers in this example shows that the nanoflowers are interconnected to form mesoporous MnO₂ with a large accessible surface area (e.g., thus offering numerous electroactive sites available to the electrolyte which promotes fast surface Faradaic reactions). FIG. 3A shows an exemplary scanning electron microscopy (SEM) image of an LSG-MnO₂ electrode at low magnification, in accordance with some embodiments.

The 3D structure of LSG-MnO₂ electrodes was further analyzed using cross-sectional SEM (FIG. 3D). The 3D porous structure of LSG is preserved after the deposition of MnO₂ without any agglomerations. The graphene surface has been uniformly coated with MnO₂ over the entire cross-section. Energy-dispersive X-ray spectroscopy (EDS), shown in FIG. 3E, provides elemental maps of C, O, and Mn, confirming that a homogeneous coating of MnO₂ throughout the 3D macroporous framework has been created. X-ray photoelectron spectroscopy (XPS) data of Mn 2p and Mn 3s are shown in FIGS. 3F and 3G, respectively, further confirming the chemical composition of the deposited oxide.

Symmetric Supercapacitors

In some embodiments, symmetric supercapacitors are constructed (e.g., fabricated or assembled) and their electrochemical performance is tested. FIGS. 4A-I show examples of symmetric LSG-MnO₂ supercapacitors 401 and their electrochemical performance. To test the electrochemical performance of LSG-MnO₂ macroporous frameworks 402, a supercapacitor pouch cell was assembled from two symmetric electrodes separated by a Celgard MX24 ion porous separator and impregnated with 1.0 M Na₂SO₄ electrolyte, as schematically shown in FIG. 4A.

Cells were tested by cyclic voltammetry (CV) over a wide range of scan rates from 1 to 1,000 mV/s. FIG. 4B shows examples of CV profiles for an LSG-MnO₂ sample with a deposition time of 3 min. The supercapacitor shows nearly rectangular CV profiles up to a scan rate of about 1,000 mV/s (e.g., as high as 1,000 mV/s), indicating excellent charge storage characteristics and ultrafast response time for the electrodes.

Capacitances of the devices made with different deposition times were calculated from CV profiles and are presented in FIG. 4C. The capacitance in FIG. 4C was calculated using the total volume of the cell stack (including the volume of the current collector, the active material, the separator, and the electrolyte), rather than a single electrode. The capacitance can depend strongly on the loading amount of the pseudocapacitive component (e.g., pseudocapacitive MnO₂). In FIG. 4C, the capacitance increases significantly with deposition time from 0 to about 960 min. For example, a stack capacitance of up to about 203 F/cm² can be achieved with the stack at the 960-minute deposition time. This stack capacitance translates to a volumetric capacitance of 1,136.5 F/cm³ when calculated based on the volume of the active material per electrode only. This value is much higher than the capacitance of, for example, activated carbons (e.g., 60-80 F/cm³), carbide-derived carbons (e.g., 180 F/cm³), bare LSG (e.g., 12 F/cm³), activated microwave exfoliated graphite oxide (MEGO) (e.g., 60 F/cm³), and liquid-mediated chemically converted graphene (CCG) films (e.g., 263.3 F/cm²), indicating that the volumetric capacitance of carbon-based electrodes can be significantly improved by incorporating pseudocapacitive materials (e.g., see TABLE 1). Furthermore, this value is higher than for MnO₂-based supercapacitors (e.g., 16.1 F/cm³ for carbon nanotube-polypropylene-MnO₂ sponge, 130 F/cm³ for graphene-MnO₂-CNT, 246 F/cm³ for CNT-MnO₂, 108 F/cm³ for mesoporous carbon/MnO₂, and 90 F/cm³ for ultraporous carbon-MnO₂). Depending on the deposition time, areal capacitances (e.g., ultrahigh areal capacitances) of up to about 0.8 F/cm² per footprint of the
device can be achieved (e.g., compared to, for example, areal capacitances of about 0.3 F/cm² provided by commercial carbon supercapacitors).  

**TABLE 1** provides examples of electrochemical performance of supercapacitors comprising a variety of electrode materials such as carbons, polymers, MnO₂, and their hybrid materials. AN (rows 1, 2, 4, and 5) refers to acetonitrile. TEABF₄ (rows 1 and 2) refers to tetraethylammonium tetrafluoroborate. EMIMBF₄ (rows 3 and 5) refers to 1-ethyl-3-methylimidazolium tetrafluoroborate. BMIMBF₄ (row 4) refers to 1-butyl-3-methylimidazolium tetrafluoroborate. For the material in row 10, the capacitance per foot print area in electrode measurements is at least two times the areal capacitance for 2 electrode measurements. For the electrode material in row 11, gravimetric capacitance is listed instead of volumetric capacitance. The LSG-MnO₂ electrode material (row 15) may be as described herein.

**[0144]** The contribution of the MnO₂ nanoflowers can be separated (e.g., separately viewed/analyzed) from the average capacitance of the LSG-MnO₂ electrodes. In an example, shown in FIG. 4D, specific capacitance of MnO₂ depends on the mass of the active material, reaching a maximum value of about 1145 F/g (about 83% of the theoretical capacitance) at a mass loading of about 13% of MnO₂. The electrode structure can facilitate the transport of ions and electrons and provide abundant surfaces for charge-transfer reactions, ensuring a greater utilization of the active materials.

**[0145]** FIG. 4E shows charge-discharge curves of an LSG-MnO₂ (3 min) supercapacitor at different current densities. MnO₂ was also electrodeposited on both CCG and gold substrates under the same conditions as the LSG-MnO₂ macroporous electrodes. FIG. 4F provides a comparison of their electrochemical performance with LSG-MnO₂. The CCG-MnO₂ electrode exhibits lower capacitance, and its performance falls off very quickly at higher charge-discharge rates. This may be attributed to the restacking of graphene sheets during the fabrication of the CCG electrodes, resulting in a significant reduction in the surface area and eventually closing off much of the porosity. The Au—MnO₂ electrode shows extremely low capacitance because of the limited surface area and structural properties (e.g., see FIG. 1A). The LSG-MnO₂ shows a stack capacitance of about 50 F/cm³ that is more than four times higher than CCG-MnO₂ and about three orders of magnitude higher than Au—MnO₂. The enhanced capacitance and rate capability of the LSG-MnO₂ can be attributed, for example, to its improved (e.g., optimized) structure (e.g., which synergizes the effects of both effective ion migration and high electroactive surface area, thus enabling high and reversible capaci-
chemical performance. The pore structure of the graphene electrode can affect the electrochemical performance of its composites with metal oxides.

[0149] FIGS. 9B and 9D schematically illustrate the effect of pore structure of graphene on its electrochemical performance for two forms of graphene of different pore structures: chemically converted graphene (CCG) films and laser-scribed graphene (LSG) films. Schematic illustrations show structural differences between dense CCG films FIG. 9A and porous LSG films FIG. 9C. Also shown in FIGS. 9B and 9D are graphs showing emergence of real (C) and imaginary (C*) parts of volumetric stack capacitance versus frequency for CCG and LSG electrodes (bottom). The CCG sheets can be well connected together in a layered structure to form the CCG electrodes. The reduced porosity and limited accessibility to electrolyte ions can cause a slow frequency response of about 5 seconds for CCG electrodes. LSG electrodes can have a well-defined porous structure such that the individual graphene sheets in the LSG network are accessible to the electrolyte, and thus exhibit a rapid frequency response of 23 ms. This may cause the enhanced capacitance and rate capability observed with the LSG-MnO2. The improved (e.g., optimized) structure of LSG electrodes may synergize the effects of both effective ion migration and high electroactive surface area, thus enabling, for example, high and reversible capacitive behavior for LSG-MnO2 even at high charge/discharge rates.

[0150] Further understanding of the capacitive behavior of the CCG/MnO2 and LSG-MnO2 hybrid electrodes was obtained by conducting AC impedance measurements in the frequency range 1 MHz to 10 mHz. FIG. 10 shows examples of Nyquist impedance plots of CCG/MnO2 and LSG-MnO2. The LSG-MnO2 shows better ion diffusion and smaller charge transfer resistance. The experiments were carried out over a frequency range of 1 MHz to 10 mHz. For each of these cells, MnO2 was electrodeposited for 120 min. The Nyquist plots consist of a spike at the low frequency region and a semicircle at the high frequency region. Compared with CCG/MnO2, the LSG-MnO2 supercapacitor shows a much smaller diameter for the semicircle, suggesting a more efficient charge transfer on the electrode surface. Furthermore, in the low frequency region, a more vertical straight line is observed for the porous LSG-MnO2 electrodes, indicating faster ion diffusion and almost ideal capacitive behavior for these electrodes. The intercept of the Nyquist plot on the real axis is about 1.5Ω, indicating a high conductivity for the electrolyte and low internal resistance of the electrodes. These results show that the microstructure of the graphene electrodes can have a strong impact on the electrochemical performance of their composites with metal oxides.

[0151] The porosity of the LSG-MnO2 can provide good accessibility to the electrolyte during charge and discharge processes while at the same time still maintaining the high packing density of the material. The high surface area of nanostructured MnO2 can provide more active sites for the Faradaic reactions and shorten the ion diffusion pathways that are crucial for realizing its full pseudocapacitance. In some examples, LSG-MnO2 electrodes can achieve both high gravimetric capacitance and volumetric capacitance superior to MnO2-based pseudocapacitors and hybrid capacitors, as described in greater detail in relation to TABLE 1.

Asymmetric Supercapacitors

[0152] In some embodiments, asymmetric supercapacitors are constructed (e.g., fabricated or assembled) and their electrochemical performance is tested.

[0153] Asymmetric supercapacitors can use positive and negative electrode materials of different types that can be charged/discharged in well-separated potential windows in the same electrolyte. Asymmetric supercapacitors may offer high capacity via a Faradaic reaction at the positive electrode and maintain fast charge/discharge due to the EDL mechanism at the negative electrode. The asymmetric configuration may extend the operating voltage window of aqueous electrolytes beyond the thermodynamic limit of water (about 1.2 V) (e.g., leading to significantly higher specific energy than symmetric supercapacitors using aqueous electrolytes). In an example, asymmetric supercapacitors may be based on carbon and NiOOH electrodes with an aqueous electrolyte. While this configuration can provide high capacitance, it can have a low cell voltage (<1.5 V) that can be detrimental to its energy and power performance.

[0154] FIGS. 5A-F show examples of an asymmetric supercapacitor based on ICCN-MnO2 as positive electrode and LSG as negative electrode and its electrochemical performance. Considering the high pseudocapacitance of the LSG-MnO2 electrode and the fast charge-discharge of the double-layer capacitance of the LSG electrode, an asymmetric supercapacitor was assembled using LSG-MnO2, S01 as the positive and LSG S02 as the negative electrode, as schematically illustrated in FIG. 5A.

[0155] In this example, a charge balance between the two electrodes was achieved by controlling the deposition time of MnO2 at the positive electrode and the thickness of the ICCN film at the negative electrode. FIGS. 5B-C show electrochemical performance of an example asymmetric cell comprising a positive electrode comprising LSG-MnO2 with 13% MnO2 mass loading (3-min deposition time). The cell exhibits an ideal capacitive behavior with nearly rectangular CV profiles and highly triangular charge/discharge curves. The CV profiles retain their rectangular shape without apparent distortions with increasing scan rates up to a rate (e.g., an ultrahigh rate) of 10,000 mV/s (e.g., indicating the high rate capability of this asymmetric supercapacitor). The asymmetric cell has a wide and stable operating potential window up to about 2.0 V in aqueous electrolyte that may afford high energy density.

[0156] FIG. 5D shows that as the MnO2 deposition time is increased from about 3 min to about 960 min, stack capacitance increases significantly from about 3 F/cm2 to about 76 F/cm2 (e.g., indicating that the stored energy and power can be greatly improved in the asymmetric structure). These cells can also retain their high capacity at faster charge and discharge rates.

[0157] The as-fabricated supercapacitor can be highly flexible and can be folded and twisted without affecting the structural integrity of the device or its electrochemical performance (FIG. 5E). Such a device may be a practical energy storage system for flexible electronics.

[0158] The asymmetric supercapacitor can have a long cycle life. The asymmetric supercapacitor can be very stable. FIG. 5F shows that the asymmetric supercapacitor can maintain greater than about 96% of its original capacity after 10,000 charge-discharge cycles tested at a (e.g., high) scan rate of 1,000 millivolts per second (mV/s). The equivalent series resistance (ESR) of the supercapacitor was moni-
tored during cycling using a Nyquist plot. A slight increase of the ESR in the first 1,000 cycles was measured, with only subtle changes over the remaining cycles.

[0159] The present disclosure provides a simple technique for the fabrication of supercapacitor arrays (e.g., for high voltage applications). The arrays can comprise interdigitated electrodes. The arrays can be integrated with solar cells for efficient energy harvesting and storage systems.

Three-Dimensional Interdigitated Microsupercapacitors

[0160] Microsupercapacitors with high capacity per footprint area may enable miniaturization of energy storage devices (e.g., for electronic applications). Greater areal capacities (e.g., than current state-of-the-art systems with areal capacities of <1.6 mF/cm²) for the non-electrolyte, <78 mF/cm² for conducting polymers, and <5.63 mF/cm² for metal oxides) may be needed. Engineering of 3D interdigitated microsupercapacitors with high energy density is described, for example, in relation to FIGS. 6A-1.

[0161] FIGS. 6A-C show an example of a hybrid microsupercapacitor in which the positive and negative electrodes are separated into a 3D interdigitated structure. This structure was achieved by combining the techniques of “top down” LightScribe lithography with “bottom up” selective electrodeposition. First, 3D interdigitated ICCN (e.g., LSG) microelectrodes are produced by the direct writing of graphene patterns 601 on GO films 602 using a consumer grade LightScribe DVD burner 603. Subsequently, MnO₂ nanoflowers 605 are selectively electrodeposited on one set of the ICCN (e.g., LSG) microelectrodes using a cell setup as described elsewhere herein. The width of the microelectrodes is adjusted to match the charge between the positive and negative poles of the microdevice.

[0162] FIG. 6D shows a digital photograph of an asymmetric microsupercapacitor 605 that consists of alternating positive and negative electrodes. The lighter microelectrodes correspond to bare ICCN (negative electrodes), whereas the other side turns darker in color after the electrodeposition of MnO₂ (positive electrodes).

[0163] FIG. 6E is an optical microscope image that shows a well-defined pattern and sharp boundaries between the microelectrodes. SEM further confirmed the conformal structure of this asymmetric microsupercapacitor.

[0164] FIG. 6F provides a magnified view at the interface between GO and graphene showing selective electrodeposition of MnO₂ on the graphene area only.

[0165] FIG. 6G provides examples of electrochemical characterizations showing that the asymmetric microsupercapacitor provides enhanced volumetric capacitance and rate capability compared to a sandwich-type asymmetric supercapacitor. Symmetric hybrid microsupercapacitors can show a similar behavior, as shown, for example, in FIGS. 6I-1, with the areal capacitance approaching about 400 mF/cm². In some examples, an interdigitated microsupercapacitor (e.g., comprising ICCN/MnO₂) has an areal capacitance of about 300 mF/cm² to about 400 mF/cm², about 350 mF/cm² to about 450 mF/cm², about 380 mF/cm² to about 550 mF/cm², or about 600 mF/cm² to about 1,000 mF/cm². The stack capacitance significantly improves to about 250 F/cm³ (volumetric capacitance per electrode is about 1197 F/cm³) which is much higher than example values for EDLC, pseudo- and hybrid microsupercapacitors: e.g., 1.3 F/cm³ for carbon oxides, 2.5-3.05 F/cm³ for graphene, 1.08 F/cm³ for CNT, 3.1 F/cm³ for graphene/CNT, 180 F/cm³ (electrode) for carbide-derived carbon, 300 mF/cm² for polyaniline nanofibers, 317 F/cm³ (electrode) for vanadium disulfide nanosheets, and 178 F/cm³ for molybdenum disulfide nanosheets (e.g., see TABLE 2).

[0166] FIG. 14A shows the full microsupercapacitor array 1401 (e.g., as fabricated by the method of FIG. 13). FIG. 14B shows an exemplary circuit illustration of the full microsupercapacitor array 1401.

[0167] FIG. 7 shows examples of energy and power density of LSG-MnO₂-based supercapacitors. FIG. 7 also shows examples of energy and power density of a number of commercially available carbon-based supercapacitors, pseudo-capacitors, hybrid supercapacitors, and Li-ion hybrid capacitors. These devices were tested under the same dynamic conditions as LSG-MnO₂. For all devices, the calculations were made based on the volume of the full cell that includes the current collector, active material, separator, and electrolyte. The energy density of the hybrid LSG-MnO₂ can vary, for example, between about 22 Wh/L and 42 Wh/L, depending on the configuration (symmetric, asymmetric and sandwich, interdigitated) and the mass loading of MnO₂. In certain embodiments, the LSG-MnO₂ hybrid supercapacitors can store at least about 6 times the capacity of state-of-the-art commercially available EDLC carbon supercapacitors. In certain embodiments, LSG-MnO₂ hybrid supercapacitors can be superior to pseudocapacitors, hybrid supercapacitors (e.g., commercially available hybrid supercapacitors comprising NiOOH positive electrode and activated carbon negative electrode, or PbO₂ positive electrode and activated carbon negative electrode; in such systems, the positive electrode may have very low electrical conductivity and thus provide little to low power density and/or the negative electrode activated carbon may have limited ion diffusion rates because of its tortuous microporous structure; such systems may only be built in large size spiral wound structures and/or may not provide capability to build high-voltage cells), and/or supercapacitor-lithium-ion battery hybrid (Li-ion capacitors). In certain embodiments, the LSG-MnO₂ supercapacitors can provide power densities up to about 10 kW/L (e.g., about 100 times faster than high-power lead acid batteries and/or about 1,000 times faster than a lithium thin-film battery).

[0168] Supercapacitors, microsupercapacitors, and/or arrays of (micro) supercapacitors herein may maintain their capacitance at high charge-discharge rates. For example, an array of supercapacitors (e.g., an array of microsupercapacitors comprising ICCN/MnO₂) can maintain its capacitance (e.g., areal capacitance) even at high charge-discharge rates. In some embodiments, a supercapacitor, microsupercapacitor and/or array of (micro) supercapacitors herein may maintain its capacitance (e.g., areal capacitance) at a charge-discharge rate corresponding to a given current density and/or scan rate (e.g., a high rate may correspond to a given current density and/or scan rate). In some examples, a supercapacitor, microsupercapacitor and/or array of (micro)
supercapacitors herein may maintain its capacitance (e.g., areal capacitance) at a current density of at least about 1,000 mA/cm², 5,000 mA/cm², or 10,000 mA/cm² (e.g., see FIG. 4F). In some examples, a supercapacitor, microsupercapacitor, and/or array of (micro) supercapacitors herein may maintain its capacitance (e.g., areal capacitance) at a current density of up to about 1,000 mA/cm², 5,000 mA/cm², or 10,000 mA/cm² (e.g., see FIG. 4F). In some examples, a supercapacitor, microsupercapacitor, and/or array of (micro) supercapacitors herein may maintain its capacitance (e.g., areal capacitance) at a scan rate of at least about 1,000 mV/s, 5,000 mV/s, or 10,000 mV/s (e.g., see FIGS. 6G-1 with a scan rate of, for example, up to about 10,000 mV/second; in certain embodiments, this translates to a charge time of about 0.1 second and discharge time of about 0.1 second). In some examples, a supercapacitor, microsupercapacitor and/or array of (micro) supercapacitors herein may maintain its capacitance (e.g., areal capacitance) at a scan rate of up to about 1,000 mV/s, 5,000 mV/s, or 10,000 mV/s (e.g., see FIGS. 6G-1 with a scan rate of, for example, up to about 10,000 mV/second; in certain embodiments, this translates to a charge time of about 0.1 second and discharge time of about 0.1 second). The supercapacitor, microsupercapacitor, and/or array of (micro) supercapacitors may maintain its capacitance at such current densities in combination with one or more such scan rates. In an example, an array of supercapacitors maintains its capacitance per footprint (e.g., at least about 380 mF/cm²) at a charge-discharge rate corresponding to (i) a current density of about 10,000 mA/cm² and/or (ii) a scan rate of up to about 10,000 mV/s.

TABLE 2 provides examples of electrochemical performance of microsupercapacitors (e.g., interdigitated microsupercapacitors). Microsupercapacitors may be, for example, interdigitated or micro-fibers. The microsupercapacitors in table TABLE 2 can include or be interdigitated microsupercapacitors. For example, the microsupercapacitors in TABLE 2 can all be interdigitated microsupercapacitors. Ionogel (row 3) refers to 1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ionic liquid gelled with fumed silica nanopowder. The LSG-MnO₂ electrode material (row 12) may be as described herein.

The present disclosure provides methods for direct fabrication of supercapacitor (e.g., microsupercapacitor) arrays for high voltage applications and integrated energy storage (e.g., as described in relation to FIGS. 8A-B).

FIG. 8A shows an array of separate electrochemical cells 801 directly fabricated in the same plane and in one step (e.g., see also FIGS. 12-16). In some embodiments, all cells (e.g., in the array) may be fabricated simultaneously in one step. This configuration may show very good control over the voltage and/or current output. In some embodiments, the array can be an asymmetric supercapacitor array. FIG. 8B also shows charge-discharge curves of examples of asymmetric supercapacitor arrays; a single device is shown for comparison. An enlarged image and additional description of the charge-discharge data is provided in relation to FIG. 17. These arrays can offer the flexibility of controlling the output voltage and current of the array. For example, compared with a single device with an operating voltage of about 2 V, an array of 3 serial cells can extend the output voltage to about 6 V; whereas the output capacity (runtime) can be increased by a factor of about 3 using an array of 3 cells connected in parallel (e.g., see FIG. 17). By using an array of 3 strings in parallel and 3 strings in series, the output voltage and current can both be tripled.

FIG. 8C shows that this array can be (e.g., in addition) integrated (or coupled) with one or more solar cells for efficient solar energy harvesting and storage. The microsupercapacitor array can store the energy produced by the
solar cell during the day and release it later whenever needed. Such a module may be applied in a variety of applications, such as, for example, for self-powered street lighting. ICCN/MnO_2 (e.g., LSG-MnO_2) hybrid supercapacitors can be integrated with solar cells (e.g., in one unit) for efficient solar energy conversion and storage. Per FIG. 8D, solar energy can be stored in an LSG-MnO_2 supercapacitor pack during the day, and charged supercapacitors can provide power after sundown. Example applications can include off-grid solar/supercapacitor power systems.

Direct Fabrication of Hybrid Microsupercapacitor Array for High Voltage Applications

[0173] Supercapacitors may be used in a variety of applications, including, for example, in applications where a large amount of power is needed for a short period of time, where a very large number of charge/discharge cycles is required and/or where a longer lifetime is required. Traditional capacitors used for general electronics applications may range from a few volts to 1 kV. The working voltage of supercapacitors may be lower (e.g., very low or <3 volts). To meet the high voltage requirements, supercapacitors can be put into a bank of cells connected together in series. This can result in bulky supercapacitor modules which can cause problems, for example, in applications where the total size of the power source is critical. The present disclosure provides an array of separate electrochemical cells directly fabricated in the same plane as shown, for example, in FIGS. 12-16 (e.g., to overcome these and/or other limitations).

[0174] In some embodiments, a method to fabricate the array of separate electrochemical cells may include a first step of fabricating an ICCN and a second step of depositing MnO_2.

[0175] Circuits can be designed using appropriate computer software and can be directly patterned on a graphite oxide film coated on a DVD disc. FIG. 12 shows a DVD 1201 after direct writing of ICCN (e.g., LSG) patterns 1202 configured (e.g., designed) to achieve symmetric and asymmetric microsupercapacitor arrays. The pattern can be designed, for example, with Microsoft Paint software and then directly patterned on a GO-coated DVD disc. In an example, the device can comprise (e.g., consist of), for example, 8 in-plane microelectrodes (4 positive and 4 negative) separated by nearly or substantially insulating GO. The distance between the microelectrodes can be suitably or sufficiently short (e.g., close enough) to keep the ion transport pathway short. In another example, patterns may be designed to make a supercapacitor bank of series/parallel combinations in order to meet the voltage (series) and current (parallel) requirements of the system on which they are to be integrated (or to which they are to be coupled).

[0176] Deposition of MnO_2 nanoflowers (e.g., performed as a second step) may comprise a deposition process that varies depending on whether a symmetric or an asymmetric array is being fabricated. Examples of such processes are described in relation to FIGS. 13-14 (for an asymmetric array) and FIG. 15 (for a symmetric array).

[0177] FIG. 13 schematically illustrates fabrication of an array of 9 asymmetric cells 1301 connected in series/parallel. A plain ICCN array can be fabricated first (e.g., as explained in relation FIG. 12). In this example, the graphene pattern is designed to make an array of 9 cells 1301 (3 in parallel x3 in series). This can be followed by electrodeposition of MnO_2 1303 in a three electrode cell as schematically illustrated in FIG. 13. For an asymmetric supercapacitor, the deposition can be controlled to go on three sets of microelectrodes (e.g., the positive electrodes) while the other three are kept intact (e.g., the negative electrodes). The deposition can be controlled such that, for example, electrodeposition occurs only on the three electrodes that are electrically connected to the power source 1302 while the other electrodes are not connected. The MnO_2 1303 deposition can occur on the 9 cells at the same time. The fabrication of the supercapacitor array may be performed approximately (e.g., almost) the same time as a single cell without the need for further processing. In some examples, at least about 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 50, 75, 100, 150, 200, 250, 500, 750, 1,000, 2,000, 5,000, 10,000, 20,000, 50,000, 75,000, or 100,000 cells may be electrodeposited or fabricated in substantially the same time as a single cell fabricated by a different method. After the deposition is complete, the supercapacitor array may be thoroughly washed with de-ionized (DI) water and/or electrolyte may be added onto each of the cells.

[0178] FIG. 15 schematically illustrates fabrication of an array of 9 symmetric supercapacitor cells 1501 connected in series and/or parallel. The fabrication method can be similar to that of FIG. 13 except that all six sets of microsupercapacitor electrodes act as the working electrode during the deposition of MnO_2 instead of the three shown in FIG. 13.

[0179] FIG. 16 shows a full set of symmetric and asymmetric supercapacitor arrays (e.g., microsupercapacitor arrays). The examples include a single asymmetric cell 1601, an array of 3 asymmetric cells in series 1602, an array of 3 symmetric cells in parallel 1603 and an array of 3 series x3 parallel asymmetric cells 1604 (from left to right, top), and a single symmetric cell 1605, an array of 3 symmetric cells in series 1606, an array of 3 symmetric cells in parallel 1607 and an array of 3 series x3 parallel symmetric cells 1608 (from left to right, bottom). A gel electrolyte may be used to prevent leakage into other cells in the array.

[0180] FIG. 17 shows examples of electrochemical performance of asymmetric supercapacitor arrays (e.g., the asymmetric supercapacitor arrays in FIG. 16 (top)). Galvanostatic charge/discharge curves of asymmetric supercapacitor arrays connected in series (“3S”) (e.g., 3 cells in series), in parallel (“3P”) (e.g., 3 cells in parallel), and in a combination of series and parallel (“3Sx3P”) (e.g., 3 series x3 parallel cells) are shown. A single device (“1 cell”) is shown for comparison. Compared with the single device with an operating voltage of about 2 V, the serial connection can extend the output voltage to about 6 V (e.g., by a factor of about 3 at about the same output capacity (runtime)) and the parallel connection can increase the output capacity (runtime) by a factor of about 3 (e.g., at about the same output voltage). By using a combination of series/parallel connections (e.g., 3Sx3P), the output voltage and current can both be increased (e.g., each by a factor of about 3 (tripled)).

[0181] The number of cells in a high-voltage supercapacitor array can be increased from, for example, a string of 3 cells (e.g., 3S and/or 3Sx3P in FIG. 17) to reach an operating voltage of, for example, at least about 100 V or other voltage(s) described elsewhere herein (e.g., in relation to high-voltage devices). For example, a high-voltage supercapacitor array (e.g., comprising ICCN/MnO_2) can have a voltage (e.g., operating voltage) of greater than or equal to about 5 V, 10 V, 15 V, 20 V, 30 V, 40 V, 50 V, 60 V, 70 V,

Solar power (e.g., solar cells; implementation in more energy efficient buildings and/or smart cities) may be combined (e.g., coupled or integrated) with an energy storage system. When combined with an energy storage system for storing energy during the day, solar cells can be used to make self-powered systems that are promising for streetlight, industrial wireless monitoring, transportation, and/or consumer electronics applications. In some implementations, chemical batteries can be used in such systems (e.g., due to their high energy density). In some implementations, supercapacitors can be used in such systems (e.g., as alternatives to batteries because they can capture energy more efficiently due to their shorter response time). Such modules may benefit from or require energy densities that are higher than the energy density of existing supercapacitors.

The present disclosure provides supercapacitors, microsupercapacitors, and/or other devices that may be integrated with solar cells. For example, a microsupercapacitor array may be integrated with solar cells. As described above, for simultaneous solar energy harvesting and storage. In some embodiments, such devices (e.g., arrays of microsupercapacitors) may achieve high voltages and/or high currents. In some implementations, such devices (e.g., hybrid supercapacitors or microsupercapacitors) may provide higher energy density. In some embodiments, such devices (e.g., hybrid microsupercapacitors) may provide any combination of high voltage, high current, higher energy density, and other characteristics (e.g., as described elsewhere herein). For example, since ICCN-MnO₂ (e.g., LSG-MnO₂) hybrid supercapacitors can provide higher energy density and can be fabricated in arrays with high voltage and current ratings, they can be integrated with solar cells for highly efficient energy harvesting and storage. An example of an ICCN-MnO₂ microsupercapacitor array integrated with one or more solar cells may be as described in relation to FIGS. 8A-8B. In some embodiments, solar cells may be grouped (e.g., in modules, panels and/or arrays). A solar cell array may comprise one or more groups of solar cells (e.g., modules and/or panels). A solar cell or a group or array of solar cells (e.g., comprising a plurality of solar cells) may be integrated or coupled (e.g., integrated in one unit, or integrated, interconnected or coupled as separate units) with one or more supercapacitors, microsupercapacitors, and/or other devices described herein.

Supercapacitors, microsupercapacitors, and/or other devices herein may be in electrical communication with one or more solar cells. The devices (e.g., microsupercapacitors) and/or the solar cell(s) may be configured in a group or array. In some embodiments, an array of microsupercapacitors (e.g., interdigitated microsupercapacitors comprising at least one electrode comprising ICCN/MnO₂) may be in electrical communication with one or more solar cells (e.g., a solar cell array). Individual solar cells (e.g., in a solar cell array) may have a given voltage. An array or group of such solar cells may have a voltage that depends on the interconnection (e.g., series and/or parallel) of the solar cells. The voltage of the solar cell group or array may be matched to the voltage of the microsupercapacitor (e.g., hybrid microsupercapacitor) array. Any aspects of the disclosure described in relation to one or more solar cells may equally apply to a group (e.g., an array, module, and/or panel) of solar cells at least in some configurations, and vice versa. In certain embodiments, a group of solar cells (e.g., a solar cell array) may have a voltage of greater than or equal to about 5 V, 10 V, 12 V, 15 V, 17 V, 20 V, 25 V, 50 V, 75 V, 100 V, 125 V, 150 V, 175 V, 200 V, 250 V, 500 V, 750 V, 1,000 V, 1,050 V, 1,100 V, 1,150 V, 1,200 V, 1,250 V, 1,300 V, 1,350 V, 1,400 V, 1,450 V, or 1,500 V. In certain embodiments, the group of solar cells (e.g., a solar cell array) may comprise at least about 1, 2, 6, 8, 10, 12, 14, 16, 18, 20, 25, 50, 75, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650, 700, 750, 800, 850, 900, 950, 1,000, 2,000, 3,000, 4,000, 5,000, 10,000, 15,000, or more solar cells.

A solar cell (e.g., one or more solar cells in a group or array of solar cells) may be of a given type (e.g., polymer and/or transparent organic photovoltaic cells, perovskite cells, organic cells, inorganic semiconductor cells, multi-junction or tandem solar cells, or any combination thereof). Solar cell(s) may be of a single junction type (e.g., comprising a single layer of light-absorbing material) or multi-junction type (e.g., comprising multiple physical configurations configured for various absorption and charge separation mechanisms). In some embodiments, solar cell(s) can comprise (e.g., wafer-based) crystalline silicon (e.g., polycrystalline or monocrystalline silicon). In some embodiments, solar cell(s) can be thin film solar cells comprising, for example, amorphous silicon, cadmium telluride (CdTe), copper indium gallium selenide (CIGS), silicon thin film (e.g., amorphous silicon), or gallium arsenide thin film (GaAs). In some embodiments, solar cell(s) may comprise other thin films and/or use organic materials (e.g., organo-metallic compounds) as well as inorganic substances. In certain embodiments, solar cell(s) may include, for example, one or more of perovskite solar cells, liquid ink cells (e.g., using kesterite and perovskite), cells capable of upconversion and downconversion (e.g., comprising lanthanide-doped materials), dye-sensitized solar cells, quantum dot solar cells, organic/polymer solar cells (e.g., organic solar cells and polymer solar cells), and adaptive cells. In some embodiments, solar cell(s) may be multi-junction or tandem cells. Further, in some embodiments, various combinations of the aforementioned solar cell types may be implemented (e.g., in a given array).

In certain embodiments, examples of solar cells may include, but are not limited to, for example, cells comprising conjugated polymers (e.g., polymers containing electron conjugated units along main chain); semi-transparent, transparent, stacked or top-illuminated organic photovoltaic cells (e.g., combining a metal nanowire network with metal oxide nanoparticles to form silver-nanowire-based composite transparent conductors that are solution-processed onto organic or polymeric photovoltaic active layers under mild processing conditions); transparent organic solar cells (e.g., visibly transparent organic photovoltaic cells); cells comprising perovskite hybrid (e.g., organic-inorganic
perovskite) materials (e.g., comprising organic-inorganic thin films fabricated through a solution process followed by a vapor treatment); perovskite-based cells employing non-doped small molecule hole transport materials (e.g., based on perovskite materials and using solution processable polymer materials as the hole and electron transport layers); amorphous silicon and polymer hybrid tandem photovoltaic cells (e.g., hybrid and/or hybrid tandem inorganic-organic solar cells fabricated by, for example, roll-to-roll manufacturing techniques); perovskite solar cells with all solution processed metal oxide transporting layers; organic solar cells; tandem solar cells; transparent solar cells; single-junction or other cells comprising conjugated polymers with selenium substituted diketopyrrolopyrrole unit (e.g., comprising a low-bandgap polymer); organic tandem photovoltaic devices connected by solution processed inorganic metal and metal oxide (e.g., comprising an interconnecting layer fabricated using a metal and metal oxide nanoparticle solution); organic photovoltaic devices incorporating gold/silica core/shell nanorods into a device active layer (e.g., devices fabricated through solution-based processing and enabling plasmonic light trapping); multiple donor/acceptor bulk heterojunction solar cells; cells (e.g., metal chalcogenide cells, such as, for example, CuInS2 cells) comprising a transparent charge collection layer (e.g., a solution processable window layer comprising titanium oxide); cells comprising electrodes comprising a highly conductive Ag nanowire mesh composite film with suitable transparency and mechanical, electrical, and optical properties (e.g., formed by a solution-based method to improve nanowires connection); cells comprising solution-processed silver nanowire-indium tin oxide nanoparticle films as a transparent conductor; cells comprising solution processed silver nanowire composite as a transparent conductor (e.g., a silver nanowire composite coating prepared using a sol-gel process as a transparent contact); copper indium gallium (di)selenide (CIGS) cells (e.g., CIGS solar cells solution-deposited by spray-coating); polarizing organic photovoltaic-based cells (e.g., tandem solar cells); cells comprising kesterite copper zinc tin chalcogenide films (e.g., fabricated through solution synthesis and deposition); or any combination thereof.

In some embodiments, a solar cell (e.g., one or more solar cells in a group or array of solar cells) and/or a group or array of solar cells may have an efficiency (e.g., energy or power conversion efficiency) of at least about 5%, 6%, 7%, 8%, 9%, 10%, 11%, 12%, 13%, 14%, 15%, 16%, 17%, 18%, 19%, 20%, 21%, 22%, 23%, 24%, 25%, 26%, 27%, 28%, 29%, 30%, or more. In certain embodiments, the solar cell(s) may have an efficiency of at least about 7%, 10.5%, 13.5%, or 15%, or from about 5% to about 7%.

Materials and Methods

Synthesis of LSG-MnO2, Au/MnO2, and CCG/MnO2 Electrodes

In one example, the LSG framework was prepared by focusing a laser beam on a DVD disc coated with graphite oxide. In an example, the laser beam is provided by a LightScribe DVD burner (GH20LS50) and has a frequency, and power of 40 milliwatts, and 730 nanometers, respectively. First, the DVD disc is covered by a film of gold coated polyimide (Astral Technology Unlimited, Inc.) or a sheet of polyethylene terephthalate. This was coated with a 2% GO dispersion in water using the doctor blade technique and left to dry for 5 hours (h) under ambient conditions. A computer-designed image is inscribed onto graphite oxide to make the appropriate LSG pattern. This was followed by electrodeposition of MnO2 from 0.02 M Mn(NO3)2 in 0.1 M NaNO3 aqueous solution using a standard three electrode setup, where a piece of LSG (1 cm²) is used as the working electrode, Ag/AgCl as the reference electrode (BASI, Indiana, USA), and a platinum foil (2 cm², Sigma-Aldrich) as the counter-electrode. The deposition was achieved by applying a constant current of 250 microamperes per square centimeter (µA/cm²) for different time periods between 3 and 960 min. After electrodeposition, the working electrode was thoroughly washed with DI water to remove the excess electrolyte and dried in an oven at 60°C for 1 h. The amount of MnO2 deposited on the LSG framework was determined from the difference in weight of the electrode before and after electrodeposition using a high precision microbalance with a readability of 1 microgram (µg) (Mettler Toledo, MXS).

For comparison, MnO2 was electrodeposited on other substrates such as gold-coated polyimide and graphene (CGG) paper. The gold-coated polyimide was obtained from Astral Technology Unlimited, Inc. (Minnesota, USA) and used without further treatment. The graphene paper was produced as described in Li D., et al., “Processable aqueous dispersions of graphene nanosheets,” Nature Nanotechnology 3:101-105 (2008), incorporated by reference herein with respect to the relevant portions therein. The gold-coated polyimide and graphene paper are cut into rectangular strips of 1 cm² for further electrodeposition of MnO2 under the same conditions as described above.

Assembly of Sandwich-Type Hybrid Supercapacitors

Hybrid supercapacitors with sandwich structure are assembled using electrodes prepared in the previous section. Both symmetric and asymmetric supercapacitors are constructed. Symmetric supercapacitors are assembled by sandwiching a Celgard MS24 (Celgard, N.C., USA) separator between two identical electrodes using 1.0 M Na2SO4 aqueous solution as the electrolyte. In the asymmetric structure, LSG-MnO2 was used as the positive electrode and LSG as the negative electrode. For the LSG- and CCG-based supercapacitors, stainless steel (or copper) tape was attached to the electrodes, using silver paint, as the current collector. Before assembly, the electrodes are soaked in the electrolyte for 1 h to ensure proper wetting. In another embodiment, per FIGS. 18A-B, the electrodes are attached using a graphene film.

Fabrication of Interdigitated Hybrid Microsupercapacitors

An example of the fabrication process of a microsupercapacitor is illustrated in FIGS. 6A-1 and described below. First, LSG interdigitated microelectrodes are inserted directly on a GO film supported on a gold-coated polyimide (or a polyethylene terephthalate) substrate using a consumer grade DVD burner. Second, MnO2 nanoflowers are grown on one set of the interdigitated electrodes using the electrodeposition setup described above. The applied current was normalized to the active LSG deposition area at a current density of 250 µA/cm² and the mass loading was controlled by adjusting the deposition time. Likewise, symmetric microsupercapacitors based on LSG-MnO2, as both the positive and the negative electrodes are prepared as well. Here, the fabrication process is the same except that the two
sides (instead of one side) of the bare interdigitated LSG electrodes are connected together using copper tape and used as the working electrode during electrodeposition. In another embodiment, per FIGS. 18A-B, the interdigitated LSG electrodes 1801 are connected together using a graphene film to form a flexible supercapacitor array.

Characterization and Measurements

[0193] The morphology and microstructure of the different electrodes were investigated by means of field emission scanning electron microscopy (JEOL 6700) equipped with energy dispersive spectroscopy (EDS) and optical microscopy (Zeiss Axiotex 100). XPS analysis was performed using a Kratos Axis Ultra DLD spectrometer. The thicknesses of the different components of the device were measured using cross-sectional scanning electron microscopy and a Dektak 6 profilometer. The electrochemical performances of the LSG-MSC supercapacitors were investigated by cyclic voltammetry (CV), galvanostatic charge/discharge tests, and electrochemical impedance spectroscopy (EIS). CV testing was performed on a VersaSTAT3 electrochemical workstation (Princeton Applied Research, USA). Charge/discharge and EIS measurements were recorded on a VMP3 workstation (Bio-logic Inc., Knoxville, Tenn.) equipped with a 10 A current booster. EIS experiments were carried out over a frequency range of 1 megahertz (MHz) to 10 millihertz (mHz) with an amplitude of 10 millivolts (mV) at open-circuit potential.

Calculations

[0194] The capacitances of the supercapacitors were calculated based on cyclic voltammetry (CV) profiles and galvanostatic charge/discharge curves (CC). For the CV technique, the capacitance was calculated by integrating the discharge current (i) vs. potential (E) plots using the following equation:

\[
C_{\text{device}} = \frac{\int i dV}{v \times \Delta E}
\]  

(1)

where \(v\) is the scan rate (V/s) and \(\Delta E\) is the operating potential window.

[0195] The capacitance was also calculated from the charge/discharge (CC) curves at different current densities using the formula:

\[
C_{\text{device}} = \frac{i_{\text{app}} \times dV/dt}{\Delta E}
\]  

(2)

where \(i_{\text{app}}\) is the current applied (in amps, A), and \(dV/dt\) is the slope of the discharge curve (in volts per second, V/s). Specific capacitances were calculated based on the area and the volume of the device stack according to the following equations:

\[
\text{Areal capacitance } (C_A) = \frac{C_{\text{device}}}{A}
\]  

(3)

\[
\text{Volumetric stack capacitance } (C_v) = \frac{C_{\text{device}}}{V}
\]  

(4)

where A and V refer to the area (cm²) and the volume (cm³) of the device, respectively. The stack capacitances (F/cm²) were calculated taking into account the volume of the device stack. This includes the active material, the current collector, and the separator with electrolyte.

[0196] The energy density of each device was obtained from the formula given in Equation (5):

\[
E = \frac{1000 \times SC \times E}{2 \times 3600 \times C_e \times \Delta E^2}
\]  

(5)

where \(E\) is the energy density in Wh/L, \(C_e\) is the volumetric stack capacitance obtained from galvanostatic charge/discharge curves using Equation (3) in F/cm² and \(\Delta E\) is the operating voltage window in volts.

[0197] The power density of each device was calculated using the equation:

\[
P = \frac{E}{t}
\]  

(6)

where \(P\) is the power density in W/L and \(t\) is the discharge time in hours.

[0198] Volumetric capacitance based on the volume of the active material only was calculated using the following equations:

\[
C_{\text{active}} = C_{\text{device}}
\]  

where \(V\) is the volume of the active material on both electrodes.

[0199] Volumetric capacitance per electrode,

\[
C_{\text{active electrode}} = \frac{4 \times C_{\text{active}}}{V}
\]  

(8)

[0200] The specific capacitance contributed by MnO₂ alone was calculated by subtracting the charge of the bare LSG framework according to the equation \(C_{\text{MnO₂}} = \frac{Q_{\text{MnO₂}}}{m_{\text{MnO₂}} \times \Delta V_{\text{MnO₂}}}\), where Q is the volumetric charge, \(\Delta V\) is the operating potential window and \(m\) is the mass.

[0201] Asymmetric supercapacitors may be configured such that there is a charge balance between the positive and negative electrodes (e.g., to achieve optimal performance with asymmetric supercapacitors). The charge stored by each electrode depends on its volumetric capacitance (\(C_v\) (electrode)), volume of the electrode (V), and the potential window in which the material operates (\(\Delta E\)).

\[
q = C_{\text{electrode}} \times V \times \Delta E
\]  

(9)

[0202] Charge balance can be attained when the following conditions are satisfied:

\[
q_{+} = q_{-}
\]  

(10)

\[
\frac{V_{+}}{V_{-}} = \frac{C_{\text{electrode}}_{-} \times \Delta E_{-}}{C_{\text{electrode}}_{+} \times \Delta E_{+}}
\]  

(11)

[0203] The charge balance was achieved by adjusting the thickness of the positive and negative electrodes.
Comparison with Commercial Energy Storage Systems

[0205] The performance of a wide range of commercially available energy storage systems was tested for comparison with LSG-MnO₂ hybrid supercapacitors and microsupercapacitors. The tested energy storage systems include, for example, activated carbon (AC) supercapacitors, a pseudocapacitor (2.6 V, 35 mF), a battery-supercapacitor hybrid (lithium ion capacitor) (2.3 V, 220 F), an aluminum electrolytic capacitor (3 V, 300 microfarads (μF)) and a lithium thin-film battery (4 V/500 microampere-hours (μAh)). Activated carbon supercapacitors of varying sizes were tested: small size (2.7 V, 0.05 F), medium size (2.7 V, 10 F), and large size (2.7 V, 350 F). The activated carbon large cell (2.7 V, 350 F) was tested at a lower current density of 160 milliamperes per cubic centimeter (mA/cm³) due to a 10 A maximum current limitation of measuring equipment. The devices were tested under the same dynamic conditions as the LSG-MnO₂ hybrid supercapacitors and microsupercapacitors.

XPS Analysis

[0206] XPS was used to analyze the chemical composition and the oxidation state of Mn in LSG-MnO₂ electrodes. The Mn 2p and Mn 3s spectra are presented in Figs. 3E-G. The peaks of Mn 2p₃/₂ and Mn 2p₁/₂ are located at 642.1 electronvolts (eV) and 653.9 eV, respectively, with a spin energy separation of 11.6 eV. Thepeak separation of the Mn 3s doublet can be related to the oxidation state of Mn in manganese oxides (e.g., 5.79 eV for MnO, 5.50 eV for MnO₂, 5.41 eV for Mn₂O₃, and 4.78 eV for MnO). The as-prepared LSG-MnO₂ showed a separation energy of 4.8 eV for the Mn 3s doublet (Fig. 3G), suggesting that the oxide is MnO₂, which was further confirmed from the O 1s spectrum.

[0207] Systems, devices, and methods herein may be adapted to other active materials. Such embodiments may enable, for example, fabrication of batteries comprising a plurality of interconnected battery cells, or other devices (e.g., photovoltaics, thermoelectrics or fuel cells) comprising cells with asymmetric electrodes.

[0208] Systems, devices, and methods herein (e.g., supercapacitors) may be used in a variety of applications, including but not limited to, for example, hybrid and electric vehicles, consumer electronics, military and space applications, and/or portable applications (e.g., smartphones, tablets, computers, etc.). Energy storage devices (e.g., high-voltage devices) herein can be compact, reliable, energy dense, charge quickly, possess both long cycle life and calendar life, or any combination thereof. In some cases, supercapacitors may be used to replace or complement batteries. For example, the hybrid supercapacitors herein may store as much charge as a lead acid battery, yet be recharged in seconds compared with hours for conventional batteries.

[0209] While preferable embodiments of the present invention have been shown and described herein, it will be obvious to those skilled in the art that such embodiments are provided by way of example only. Numerous variations, changes, and substitutions will now occur to those skilled in the art without departing from the invention. It should be understood that various alternatives to the embodiments of the invention described herein may be employed in practicing the invention. It is intended that the following claims define the scope of the invention and that methods and structures within the scope of these claims and their equivalents be covered thereby.

What is claimed is:

1. An electrochemical system, comprising a planar array of interconnected electrochemical cells, wherein each electrochemical cell comprises at least two electrodes, wherein each electrode comprises a carbonaceous material, wherein at least one electrode further comprises a pseudocapacitive material.

2. The electrochemical system of claim 1, wherein the carbonaceous material comprises an interconnected corrugated carbon-based network (ICCN), a laser scribed graphene (LSG) or any combination thereof.

3. The electrochemical system of claim 1, wherein each electrochemical cell comprises two electrodes, and wherein each electrode comprises a carbonaceous material and a pseudocapacitive material.

4. The electrochemical system of claim 1, wherein the pseudocapacitive material comprises MnO₂, RuO₂, Co₃O₄, NiO, Fe₂O₃, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof.

5. The electrochemical system of claim 1, wherein the planar array of interconnected electrochemical cells is arranged in an interdigitated structure.

6. The electrochemical system of claim 1, further comprising an electrolyte disposed between the at least two electrodes.

7. The electrochemical system of claim 1, further comprising a current collector attached to an electrode.

8. The electrochemical system of claim 1, wherein at least one electrochemical cell is capable of outputting a voltage of at least about 5 volts.

9. The electrochemical system of claim 1, wherein the electrochemical system is capable of outputting a voltage of at least about 100 volts.

10. The electrochemical system of claim 1, wherein an electrochemical cell has an energy density of at least about 22 watt-hours per liter (Wh/L).

11. The electrochemical system of claim 1, wherein the planar array of interconnected electrochemical cells has a capacitance per footprint of at least about 380 millifarads per square centimeter (mF/cm²).

12. The electrochemical system of claim 1, wherein the planar array of interconnected electrochemical cells has a volumetric capacitance of at least about 1,100 farads per cubic centimeter (F/cm³).

13. A method for fabricating an electrochemical system, comprising:

   forming a carbonaceous film;
   forming a carbonaceous framework from the carbonaceous film;
   patterning the carbonaceous framework to form an array of two or more cells, wherein each cell comprises at least two electrodes; and
   electrodepositing a pseudocapacitive material onto a portion of the array.

14. The method of claim 13, wherein the carbonaceous film comprises graphene oxide (GO).

15. The method of claim 13, wherein the carbonaceous film comprises a three dimensional carbon framework comprising an interconnected corrugated carbon-based network (ICCN), a laser scribed graphene (LSG), or any combination thereof.
16. The method of claim 13, wherein the forming of the carbonaceous framework from the carbonaceous film comprises light scribing.

17. The method of claim 13, wherein the patterning the carbonaceous framework comprises light scribing.

18. The method of claim 13, wherein the patterning the carbonaceous framework forms two or more interdigitated electrodes.

19. The method of claim 13, wherein the array is a planar array.

20. The method of claim 13, wherein the pseudocapacitive material comprises MnO₂, RuO₂, Co₃O₄, NiO, Fe₃O₄, CuO, MoO₃, V₂O₅, Ni(OH)₂, or any combination thereof.

21. The method of claim 13, further comprising depositing an electrolyte on the carbonaceous framework.

22. The method of claim 13, further comprising connecting two or more cells within the array.
